"Equally famous is *O. ficus-indica*, the 'Indian fig' cactus. This species has escaped from cultivation and has become naturalized in a few places in south Florida, especially on Key West. It, also, is very hardy, and would doubtless prove so in north Florida. It is a most striking and picturesque plant, attaining, in a few years from the cutting, a height of 10 or 12 feet, with immense flat joints a foot or even 14 inches in length. The scale-like spines often drop off and leave the surface perfectly smooth, so it is not very prickly nor difficult to handle. The fruits are larger than those of *Opuntia tuna*, and are yellow in color. The pulp is sweet and has very few seeds. It is very much liked by most people who are familiar with it, and we have seen those who preferred it to such popular and delicious fruits as the orange and banana. The fruit is

annual report of the California State Board of Horticulture for 1890, page 133, and elsewhere. In the same report is given a plate illustrating the fruit of the *tuna colorado* and the *tuna manse*, and also of the wild tuna (*Opuntia engelmannii*). See engravings used herewith.

Gerald Haetinge (*American Garden*, XI, 475) says: "Several species of *Opuntia*, particularly *O. tuna*, yield the red, green or yellow fruits known as prickly pears. These are sweet and juicy and extensively used as dessert by the Mexicans and inhabitants of Southern Europe. Their juice is used as a water-color at Naples, and for coloring confectionery in the West Indies."

OPUNTIA FICUS INDICA—Haworth.

"During the eighteenth century Mr. Philip Miller of Chelsea Gardens, England, brought several cacti into notice, at least eight being credited to him and described in his *Gardener's Dictionary* in addition to those already known. Martyn's edition of Miller's *Gardener's Dictionary* enumerates, among others, *Cactus ficus indica* and *O. tuna*. Not having access to the above works, I am unable to learn with any degree of certainty as to the characteristics of the types of these species. Apparently the most reliable description accessible to me is in Forester's 'Cactaceae,' of which the following is a free translation:

"Native of South America, cultivated south of the Rio Grande under the name *Nopal castillano*; naturalized in Italy and Sicily; tall,

dian learns to handle these fruits with utter indifference to the spines.

The spines are abundant and rather formidable in appearance on this beautiful plant, but are really one of the most useful characteristics of the plant, making it very useful for hedges and fences.

OPUNTIA "TUNA-MANSE."

The color of the fruit of this *tuna* outside is of a deep ochraceous-buff, slightly glaucous, irregularly mottled and blotched with crimson, giving it a bloodshot appearance; inside the outer coating is of the same coloring, but the pulp inclosing the seeds is of a light greenish-yellow.

This is the most abundant of the three forms of *tunas* naturalized at the San Diego Mission, and like the others is credited with a Mexican nativity. The fruit is nearly globose, with a yellowish umbilical, pitted in the center, an inch in diameter and smaller proportionally than in *tuna* or *tuna colorado*. Seeds more numerous (about 250). Areolae and spines on fruit and stem differ but slightly if any from *O. tuna*, from which the plants may not be readily distinguished except when in fruit.

[The manner of growth of this species is shown in the engraving, showing a column with the figure of a man central, thus indicating the size the plant attains. The cuts of the three species of fruit are from B. M. Lelong's report for 1890, as noted above.—EDS. PRESS.]

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

HARDENBURG.—*Ledger*, Feb. 28: Grading for a millsite was commenced at this mine at Middle Bar on Monday. We understand it is intended to put up a 15-stamp mill, and the stamps of the old mill now on the claim will be utilized in the new structure. The stamps are light, 600 or 650 pounds, but it is the opinion of many expert millmen that better results are obtained from light than from heavy stamps, the tendency of the latter being to create such strong commotion as to cause a greater loss of gold. The mill is to be put up near the shaft, and is well located for water-power, the pressure being ample. James White, who superintended the construction of the Amador mill, has charge of putting up this mill.

GOVER.—At the Gover they have succeeded in getting their 700-foot level cleared of water the first time since it was flooded six years ago. At that time they put in a large bulkhead in their north drift where their water came in, and for two weeks it held the water back; then it made its appearance 40 feet this side at the rate of 75,000 gallons per 24 hours. This flooded their lower levels again and during these last six years they have never been able to get this level cleared again. For the last two months they have been pumping and skipping water, and last Friday, the 20th, they cleared the level and found that the place where water broke in, 40 feet this side of the dam, had choked up by drawing the water down and didn't leak a drop. At present time water has been confined nearly a week, and instead of breaking into the mine again has made its appearance half a mile north in an old tunnel which, when the mine was flooded, was dry. This is a most important fact to the Gover people, as they can now easily control the surface water, and they will immediately open out their lower levels where the original Gover Co. abandoned rich ore when the mine was flooded. It is also reported that they have struck another pay chute on their 500-foot level.

BELMONT MINE.—At this mine the surface tunnel has been driven 20 feet the last week; total distance, 120 feet; 50 feet have yet to be driven before ore is reached and the company's 10-stamp mill can be started.

MISCELLANEOUS.—No further developments have been made in the Bell Wether or Bright mine. Little has been done this week, owing to the fact that machinery is necessary to the further prosecution of work. A horse-power whim has been purchased from the Live Oak mine on Stony creek and has been moved to this claim and will be erected forthwith. A. O. Wilcox, who has been running a roller mill at the Beardslee cement gravel claim, Upper Rancheria, for several weeks, got down to his old stamping-grounds in Jackson last Saturday. He reports that the auriferous cement carries about \$3 worth of gold to the ton, at which rate it ought to yield a fair profit. E. E. Dye, in charge of the Amador gold mine, went to San Francisco last week to arrange for the payment of taxes upon the property, and other business. He returned Tuesday night to find that the property had been sold that day for delinquent taxes to G. Quirolo. The buyer is entitled to 50 per cent advance on the purchase price, so that the taxes and costs now run up to over \$100. The property was among the first on the list, and as the tax-collector must offer each parcel in rotation, it was one of the first offered and the bid was jumped at as a solid investment. The property will of course be redeemed before long.

Del Norte.

THE BEACH MINES.—*Del Norte Record*, Feb. 21: Last Sunday our representative, accompanied by that veteran Black Sand miner, Col. Yates, made a trip down the beach to where the black sand mines of Messrs. Raymond and Lhote are located, to view the manner in which the gold is obtained from the auriferous black sand by the machine used at this mine. Arriving at the mines, we find the engine and machine under a shed, while the men are kept busy wheeling harrows up a runway to a platform alongside the top of the machine where the sand is dumped and fed into the machine by the shovelful by the feeder. As this machine is built and operated on an entirely different process from that used by the beach mines in this neighborhood a number of years ago, we give the following description: The machine stands about seven feet high, with four arms running from the center of a shaft, about three feet from the ground; these arms are about four feet long and each supports a pan about 2½ feet in diameter; above this about two feet is a large pan built so as to cover the center of the lower pans. The sand was fed with a shovel into a hopper, into which a stream of water ran from an inch pipe. A screen immediately under the hopper screened out the gravel. This sand was washed through a discharge pipe into the circular pans below. These pans are double ones, consisting of an outer and inner pan. The inner pans are shallow, circular, and made of copper, the surface of which was silvered and coated with mercury; they are suspended within an outer and deeper copper pan, the surface of which is also silvered and amalgamated. The water and sand flow down upon the inner pans, to which, by the revolution a motion is given similar to that of a pan worked by hand. The gold is caught upon the surface of the inner pan, while the sand runs out into the tailing-box. The screen on this machine is the invention of C. W. Babcock of this city; and on account of the pebbles and gravel found in the sand, it would be impossible to run the machine were it not for this attachment. This machine has a capacity of about 80 tons a day; at present they are running with a force of six men.

Nevada.

THE MINES ARE ALL RIGHT.—*Grass Valley Union*, Feb. 26: The late storms of rain and snow have not materially interfered with mining operations in this district, but little if any extra water coming from the surface has given the mining pumps more than their usual work to perform. The water supply for power, has not been interfered with, as the source of supply, the South Yuba canal, has not been broken or snow-blockaded, as was the case at this time last year. At that time all the mines of the district were being flooded with

water, and it was a hard and long struggle to prevent them from being drowned out.

THE PEABODY.—*Grass Valley Union*, Feb. 26: A cleanup of 55 tons of ore from the Peabody mine was made at the Crown Point mill on Monday, which gave a result of \$25 per ton. This was entirely satisfactory as showing the quality of the ore produced by the mine. The Peabody Co. will soon commence making important improvements on the mine by sinking a new three-compartment shaft between 400 and 500 feet west of the present shaft, and the erection of new pumping and hoisting works, which will be operated by steam-power. This shaft will be constructed in the most substantial manner, with a view to the permanent development of the mine. The shaft will be sunk from the surface and an upraise also made to it from the No. 3 level below, which has been run far enough to the west so that a connection can be made with the new shaft. The operations which have been carried on for the past year have been mainly for prospecting purposes, and the mine has now been opened sufficiently and is showing so well that the sinking of a new shaft is warranted, as it is found that the old shaft is not located in the right place. During the progress of sinking the new shaft, the work of hoisting ore through the old shaft will go on as heretofore. With the new shaft and with new hoisting and pumping works the Peabody will be well equipped for further operations.

CALIFORNIA.—The California M. Co., recently incorporated to work the Pittsburg mine, on Deadman's Flat, has had its 20,000 shares set aside to raise a working capital promptly subscribed for, the whole amount having been taken. These shares were taken at Grass Valley, Marysville, San Francisco and San Jose. After they were taken, an order came from Chihuahua, Mexico, for 5000 shares, sent by Grass Valley men who are employed in the railroad shops at that place. The company is now placed in funds for its preliminary operations, and should it be found that more capital will be necessary, there are yet remaining 20,000 shares that can be used for raising additional capital, but this will not be disposed of at less than 50 cents a share. The mine has a good record as a prospecting operation, is well located in a portion of the district where the mines are doing well and are held in high favor, and there is every reason to believe that it will open up well as soon as the new works are put up and the shaft and drifts can be put in shape for systematic exploitation.

Napa.

A VALUABLE MINE.—*Calistogan*, Feb. 18: B. M. Newcomb, superintendent of the Napa Con. Quicksilver mine, has sent to us the following report of business done at the mine during the past year:

Cash disbursed.....	\$119,157
Total payroll.....	104,629
Paid for farm products.....	15,800
Wood and lumber account.....	21,748
For building roads.....	3,120

During the year 17,770 tons of ore were mined and treated, from which 2700 flasks of quicksilver were obtained, the weight of the metal being 206,550 pounds. Credited to the work of development are the following items: Tunnels and drifts, 8800 feet; shafts and winzes, 1000 feet. The N. C. is one of the most valuable quicksilver mines on the coast, and from present indications will annually furnish a large amount of metal several years to come. That the mine is located within the borders of Napa Co. is a fact we are pleased to mention in this connection.

GOOD PROSPECTS.—The work of prospecting on ground formerly included with property of the old Calistoga G. & S. M. Co., on the side of Mount St. Helena, has been going on the past few months, Dan Patton and others interested believing that plenty of good ore is there if it could be found. The indications now are very good that their efforts will be crowned with success. The prospect work is being done near the excavations made years ago in the old mine. In excavations recently made a vein about two feet wide has been encountered, and from it good milling ore has been taken, some of it being high-grade. Greater depth will be necessary to prove the value of the vein, but as the prospects are good the necessary work will be most cheerfully done. There is plenty of ore in the old mountain and we hope the company now looking for it will succeed.

Placers.

THE LAND OF GOLD.—*Herald*, Feb. 28: Last Monday morning after the unprecedented hard storm of the night before which washed the streets and gullies clear of soil, the gold-hunters were out in force. Quite a number of pieces were picked up in different parts of the city, varying in value from a few cents to a few dollars. The largest find reported was by Katie Deekin, who picked up a piece in the road out near Ames' place worth some \$6 or \$8. The value of all the pieces picked up here in the city would probably exceed \$20. California is truly the land of gold. In Auburn they literally pick it up in the streets.

Plumas.

GIBSONVILLE.—*Cor. Plumas National*, Feb. 28: No doubt the mining men will be glad to hear that bedrock was struck in the Thistle shaft, last Sunday. They have fine-looking gravel and it prospects well. The shaft will be completed in a few days, if nothing happens to prevent them working. They will then commence running tunnels off from the bottom of the shaft. The workmen, while repairing the North American mine, have found that the bad air which caused Mr. Mark Schofield's death was caused by a fire in the mine at the No. 3 turnout, where a great number of timbers were piled. It is generally supposed that the fire was set by some unknown party, although it might have been an accident or an explosion of gas.

Siskiyou.

HONOLULU.—*Siskiyou Telegram*, Feb. 28: Henry Mack of Honolulu was in the city for a short time last Wednesday, while en route for Fort Jones. He informs us that the majority of the mines on the Klamath will be worked this season. The Phil Mott claim, in which Mack is interested, will be operated on a larger scale than ever this season. The majority of the companies are at present in the woods cutting the necessary timber for constructing their windmills. We look for some good results from Klamath this year. We understand that the Centennial mine at Honolulu, on the Klamath river,

will be operated quite extensively during the coming spring and summer. It is the intention of the owners to open up farther up stream than ever before, and near the Bentz Bar mine, which is operated very successfully by a Chinese company. Gott & Co., the owners of the Centennial, have persistently worked it for years, with varied degrees of success, and expect to do much better on their present location.

AURIFEROUS GRAVEL.—*Yreka Journal*, Feb. 26: Frank H. Hall, consulting engineer, of San Francisco, is now cutting through the rimrock in the old August diggings at Quartz Valley, where he expects to tap an old dead river channel containing an immense body of auriferous gravel, believed to be exceedingly rich, and which extends from Callahans along the west side of Scott River to the canyon and thence to Scott Bar. Louis Guilbert of Yreka has been at work lately sinking a mining shaft in a claim located east of the Shasta Valley road, about three miles south of town in the Kildore hills, near the old Oak Grove race-track, and has found colors all the way down, with improving prospects at a depth of 30 feet. No signs of bedrock are yet visible, although bedrock crops up at the gulch near the wagon-road, where considerable gold was taken out in 1854. Louis thinks the indications are very favorable for tapping the famous blue gravel channel, which undoubtedly extends along the east side of Yreka to mouth of Greenhorn and out into Shasta valley. E. Dudley and others have also taken up claims in the Kildore hills, close by Guilbert's location, and will also commence prospecting by assisting Louis to get down to the bedrock, which will be the best means of ascertaining the certainty of the existence of a dead channel containing gold.

QUARTZ.—The quartz-mill on Yreka Flats will soon be moved farther northward on the flats in the vicinity of Long Gulch, where there are a number of rich and extensive ledges, which the owners intend opening on a large scale during the coming summer. The quartz-miners at head of Greenhorn creek and on Cherry creek, on the Greenhorn and Deadwood divide, are also anxious to have a custom-mill put up in that section, and guarantee to furnish a good supply of quartz for crushing, the hauling for long distances being quite expensive and slow, owing to the steep grades required in reaching the various mountain ledges.

RIVER MINING.—The river-miners on the Klamath are still at work in taking out pay gravel, notwithstanding the storms of the past week, which have not raised the stream over a foot higher. They will probably be able to continue work right along, as it is too late in the season now for the possibility of any freshets likely to interfere with the windmills that have been in use all winter.

Sierra.

SIERRA CITY.—*Mountain Messenger*, Feb. 28: There are 15 then working at the Colombo; Cleveland, 20; Young America, 80; and Berger's ledge, 30. Only two men are employed by the Sierra Buttes Co. Jos. Carney is in charge of the flume and lakes, and Stephen Thomas, office, buildings, No. nine mill and mine. The upper 20-stamp mill will be rebuilt next April. Two men are getting out rock at the Wm. Tell ledge. The six-stamp mill is to be started as soon as sufficient water comes. Milling ore already crushed averaged \$20 a ton. Average yield, through the ledge, as far as developed, \$7 a ton. R. A. Grass, one of the stockholders, is superintendent.

Trinity.

RUNNING ON FULL TIME.—*Journal*, Feb. 21: Mr. W. J. Grigshy, who was in town the first of this week, informs us that the Buck's Ranch Mining Co. has extended its ditch to the main East Fork creek, a distance of about 2½ miles. This will give them a good supply of water for the entire year. They are now running their mill day and night and getting satisfactory results. The ledge can be worked very cheaply and very low-grade rock can be crushed with a profit. This company has the widest ledge on the creek, and with the facilities they now have for working it there is no doubt that a handsome profit will be realized.

NEW RIVER.—Capt. James Franzen arrived in Eureka from New River last week and informed the Standard that the superintending officers of the Ridgeway mine were anxious to have him remain a day or two longer, believing that daylight would be struck through the upraise in that promising mine within that time. All was anticipation in connection with that event, the general belief being that it was the forerunner of an important era in the history of the Ridgeway, from which golden returns are expected when the upraise work is completed. Capt. Franzen says that although times were comparatively dull, work was being prosecuted in some dozen mines in the district.

GRAVEL MINES.—*Redding Free Press*, Feb. 28: Billy Fowler the mining man has just returned from Trinity county, where he has been visiting the gravel mine of the Trinity Gravel Co. on the Trinity river. They have four giants running and expect to make a good cleanup at the close of the season. Mr. Fowler thinks that the recent law making the Klamath river not navigable will stimulate hydraulic mining in Trinity county and enable impecunious mine-owners to sell good properties to capitalists who heretofore have held aloof for fear of injunctions. Speaking of the Jillson gravel claim near Hornbrook, Mr. Fowler informs us that during a run of five days \$550 was taken out of the boxes, including one solid chunk of gold valued at \$130. Mr. Fowler insists upon it that this same blue gravel lead runs through a portion of this county, and that in the near future there will be some astonishing developments.

Ventura.

GYPSUM.—*Ventura Free Press*, Feb. 20: Superintendent E. Twining, who was in Ventura yesterday, said that the Ventura Plaster Co. had no intention of shutting down their mine on the Ojai, but on the contrary would increase the force as soon as they could work conveniently. The mine is being worked from a shaft with drifts leading away from it at a certain level. Several weeks ago it was found that more gypsum could be secured by going deeper, so those men working in the drifts were laid off. The remaining men were put to work sinking the shaft and in a short time a larger force will be put at work. The factory at San Francisco wants 50 tons a day, but thus far the Ojai mine has been unable to supply more than a quarter that amount. It is for the purpose of securing a greater supply that a mine is being opened in Orange county.

WILL REFINER ASPHALTUM.—The Ventura As-

phalt Co. is building refinery works on a vacant lot near the depot, and early next week will be ready to use a large quantity of rock. Thos. Moran of den, Utah, is here superintending the works.

NEVADA.

Washoe District.

BELCHER.—*Virginia Enterprise*, Feb. 28: resumed work in the north drift from No. 3 crosscut, 200 level, which is out a total distance 131 feet. The face is composed of clay. No. 2 west crosscut, 300 level, advanced 23 feet; length, 100 feet. The face is in porphyry. 1400 level east crosscut is out 73 feet. It reached what looks like the hanging wall. The width of about 20 inches of quartz next to wall, which contains bunches of good ore.

UTAH.—On the 725 level the northwest drift making the usual progress in ground of a favorable appearance. West crosscut No. 2 is in vein material that shows a good deal of quartz.

WARD COMBINATION.—The east drift on 1800 level is in a clay and porphyry formation.

CHALLENGE AND CONFIDENCE.—The north east crosscut, 300 level, is in 6 feet, having commenced during the week; the face shows quartz having no value.

ANDES.—During the past week north winze 350 level was sunk 11 feet. No change in location. North drift on 420 level was extended 16 in a formation of quartz, clay and porphyry.

GOULD & CURRY.—200 level: From bottom of winze No. 1 started a south drift on a small strip of quartz showing some ore; extended same to 140 feet. We have extracted from winze during the week cars of ore of a fair quality. 250 level: South from upraise has been advanced 10 feet; total length, 41 feet. Face in quartz and porphyry. West cut No. 1 from upraise has been advanced 11 total length, 97 feet. Face in soft porphyry showing bunches of quartz. 300 level: Carried up incline upraise No. 2, 12 feet and made connection with crosscut No. 3 on 200 level, thereby improving the ventilation of this section of the mine.

BEST & BELCHER.—800 level: West crosscut No. 2 has been extended 18 feet, through porphyry and quartz; total length, 504 feet. 1200 level: West crosscut No. 1 has been advanced 18 feet; total length, 140 feet. Face in porphyry, clay quartz.

POTOSI.—On the 930 level the east crosscut of the winze is still in porphyry that contains streaks of quartz. On the 1230 level the east crosscut, feet south of the Chollar incline, is in porphyry showing bunches of quartz. On the 1300 level, south lateral drift is showing clay in the porphyry. All is now in shape for a thorough exploration this level.

HALE & NORCROSS.—The usual prospecting operations are in progress on the 800, 900, 1100 and 1400 levels. At some points material of a promising appearance has been encountered. The repair of the main incline below the 1400 station are making good progress; also work on ore and waste chutes.

OPHIR.—The west crosscut on the 1300 level still in a material that carries some metal.

UNION CON.—East crosscut No. 2 on the 1 level continues in a clay and porphyry formation.

MEXICAN.—On the 1455 level No. 1 crosscut is advancing in a porphyry formation.

CON. CAL. & VA.—Are extracting ore from 1200, 1300, 1500, 1600 and 1650 levels. Good headway is being made in the south drift on 1100 level from the Con. Virginia shaft. It is in porphyry, and has yet a considerable distance to go before reaching a point where ore is expected. The usual amount of ore has been extracted sent to the mills, and the average assay value will about the same as last week.

JUSTICE.—The north drift on the 822 level is 356 feet. The face is in hard rock. Have done work on the 490 south drift during the week. S. ped to the mill 202 tons and 315 pounds of Average battery assay, \$75.66 per ton. Have speeded the extraction of ore, pending the connection of the 822 drift with the bottom of the 622 winze.

SAVAGE.—During the week we have hoisted carloads of ore from the 400, 500, 750 and 1100 levels, and from the intermediate level below 1300 level. Shipped to the Mexican mill 540 tons and milled 540 tons of ore, the average battery assay of which was \$15.60 a ton. We have hauled on hand amounting to \$18,670.20. We have resumed work in the bottom of the winze below 1300 level, and have sunk the same 20 feet, making its total depth 103 feet below sill floor 1300 level. From the Hale & Norcross north drift, 900 level which is 90 feet in Savage ground, we have commenced stoping ore in east crosscut No. 1. The body shows a width of 18 feet of fair-grade, mixed with some porphyry. We are extending the Hale & Norcross drift, 800 level, from south boundary into the Savage ground. This is now advanced 30 feet, and is encountering fair-grade ore on the east side of the drift.

SILVER HILL.—Good headway is making in opening out on the 500 level.

CON. IMPERIAL.—Work is still being confined following up and taking out small streams of ore on the upper levels and overhauling the old stope of mine.

ALPHA & EXCHEQUER.—The only work done was in repairs to the main shaft.

SEG. BELCHER.—The east crosscut from south lateral drift on the 600 level was advanced feet since last report, making its total length 69 feet. The face is composed principally of clay.

OCCIDENTAL.—Ore of good quality is being found in both south drifts of the 400 level.

SIERRA NEVADA.—630 level: The north drift is still in a porphyry formation.

OVERMAN.—Extracted 386 tons and 800 pounds of ore. Car sample assays average \$75.70 per ton. Shipped to the Brannish mill 46 tons and pounds of ore. Battery samples average \$76.60 per ton. On the 1100-foot level the incline up from the northwest drift has been extended 9 feet total length, 173 feet. At a point 165 feet up commenced to cut a station, and when complete will start a drift to the northward to connect with the southwest drift from the shaft. Incline up from the south drift has been extended 17 through quartz of a fair grade; total length, 100 feet. On the 1200 level southeast drift, on eighth floor of stope, has been extended 26 feet through quartz; total length, 94 feet.

KENTUCK.—During the week we have put

in the raise, 1000-foot level east ledge, and
and the raise 5 feet, making its total height 33
The top is all low-grade quartz. Continued
north drift on this level to the north line of the
and started an east crosscut from the end of it
high quartz containing some spots of ore which
aved for pay. The north drift from the west
advanced 10 feet, making its total length 19
The face is in low-grade quartz.

COLLAR.—Winze 80 feet south of north line,
level, is still going down in a mixture of quartz,
and porphyry. Good progress is making in
work of opening the station on the incline at the
level. The ore sent to the mill will average
on ton.

CROWN POINT.—The west crosscut on the 500-
level has been advanced 25 feet since last re-
port, length, 92 feet. The face is composed
of porphyry, with small seams of quartz through
are still engaged on repairs on the 600 level.

Tuscarora District.

YADA QUEEN.—*Times-Review*, Feb. 27:
on drift, 650-foot level, advanced 32 feet, show-
ing slight improvement.

VAJO.—East crosscut from north end of the
lateral, 350-foot level, is in 20 feet. Have
an intermediate drift from No. 5 chute,
level.

COMMONWEALTH.—Fourth level: East crosscut
now extended 36 feet, cutting seams of spar
and some water. West crosscut advanced 40
feet hanging-wall, will now start to open up
by this crosscut.

LE ISLE.—South drift, 450-foot level, ex-
tended 25 feet; the face is looking more favorable.
Main crosscut, same level, has been extended
40 feet; a little water is beginning to show in the
drift. The stope above the 350 continue in
grade ore. Broke 8 cars of high grade and 23
of concentrating ore.

ORTH BELLE ISLE.—North drift from Belle
450-foot level, extended 14 feet, no particular
change. The 500 stope continue to look well.
Broke 7 1/2 cars of first class and 37 cars of concen-
trating ore. No. 4 upraise from the 600-foot level
has been extended 16 feet; the top is all in quartz,
giving some good ore.

ORTH COMMONWEALTH.—Hoisted during the
21 tons of ore, average \$265 per ton, and 68
tons assaying \$20 per ton.

Oscoda District.

ORE.—*Salt Lake Tribune*, Feb. 28: The
mine some time ago noted the arrival of gold ore
from Oscoda, Nev., from some mines which Messrs.
Ham & Raddatz had purchased from Duff
Bros. Assays were made from four samples of
ore and they ran respectively in gold \$30, \$24,
\$18 and \$8, which is certainly excellent for free-
zing gold ore when it is in such immense quanti-
ties it is said to be in the Oscoda ledges. The
managers of this group have been negotiating with
Boston parties, who have agreed to purchase
the property if it is as good as the assays have shown,
or for the purpose of demonstrating this, 150 lbs of
ore was sent yesterday by express to the Boston par-

Pahranaagat Lake District.

TURNED.—*Pioche Record*, Feb. 26: Messrs.
Silvia and Geo. S. Barber, who two months
ago took a bond on the Balback mine, Pahranaagat
district, and went down to work on the claim,
have thrown up the work. The lessees say the
mine is a good prospect but not rich enough to
justify work in the face of such unreasonable diffi-
culties as they encountered, so they threw up the
mine and returned last week to town with their
tools.

ARIZONA.

OTES.—*Prescott Courier*, Feb. 26: D. Boaz
has been "looking the gold field over" in Big Bug,
and says the district has a fine metallic future. He
loves with the Boggs, Silver Bell, Gladstone and
other mines. Chloride Jack's bonanza is in
good health. W. H. Harlan, discoverer of the
Howard vein, is still in the shaft, taking out
and paying ore. Slate Creek miners have shed
their tools and will soon make large shipments of high-
grade ore. Jack McDonald, John Sugden, Nels
Gie, all of them have put on extra men. Crowned
King is shipping much ore and sulphur to the
Elaso smelter. Tiger mine is yielding high-grade
ore. Turkey creek miners are prepared to ship
fine ore. J. J. Williams reports fair progress
in several camps. Jennings, of Hassayampa,
wishes he had a mill to pound gold out of his
mine. Mr. Potter, a Michigan capitalist, is negotiat-
ing for certain mining property near Walnut Grove.
Lix creek hydraulic works are in full blast. Weav-
ers are making fair wages. Machinery for a
stamp mill was at Aztec, a few days ago, en
route to Harqua-Hala.

OHAVE NOTES.—*Miner*, Feb. 28: Jas. Mc-
Gor has made another strike on his claim at El
Dado canyon. Joe Labaree and James Cadden
are extracting good, rich ore from the Diana mine
in chloride. A. James will put a force of men at
work on the Bull Dog mine in Todd Basin stoping
ore. The pumps in the Cupel mine are slowly
raising the water and sinking will be commenced
in a few days. It is rumored that several Mohave
county mines will be incorporated in Los Angeles
at the stock placed upon the market in a few
days. Butolph and Grant have taken charge of
the Mexican mine in Todd Basin, and will place a
force of men thereon taking out the rich gold ore on
the surface. Geo. M. Bowers will have several tons
of ore from the Nighthawk dumps concentrated at
the James mill in Todd Basin. Supt. Butolph of
the Denver M. & Co. has a carload of ore ready
to be dumped of the Homestake mine in Mineral
Pk. From Wm. Heimrod, who is now in charge
of the mill at El Dorado canyon, we learn that a
strike of ore rich in both gold and silver has
been made in the Charleston mountains, on Indian
creek, about 100 miles northwest of the canyon in
the vicinity of Death Valley. The contract on the
Gen Bee mine is almost completed, and as soon
as the hoist can be put in place 30 or 40 men will
be set to work in the stope. James Carter, from
Ced Basin, informs us that the mill, under the able
management of Lew Lassel, has been running suc-
cessfully. Fred Brown is stoping a great deal of rich
silver-lead ore from the Indian Boy. In the Altatta,
Coride, Koster and McKinnon they have at last
rebed the ore body in the drift they have been

driving and they are rewarded by exposing two feet
of richer ore than was ever before produced from
that mine. The ore is silver, showing a great deal
of native copper. At the Empire, E. F. Thompson
has between 40 and 50 tons of very rich ore on the
dump awaiting shipment.

DOS CABEZAS.—*Cor. Tombstone Epitaph*, Feb.
25: We have up to this time had a singularly open
winter here. Even on the mountains 7000 to 8000
feet above the sea level our deepest snow has been
six inches, and, except in small patches on northerly
slopes, that is all gone. The quartz-mill at this
place has had a profitable run recently on 70 tons of
gold ore from the Ewell Springs lode. The yield was
somewhere about \$15 or \$16 per ton. This ore was
mined by Fowler & McGregor and was carefully as-
sorted. For each ton of selected ore about three
tons of barren and lower grade rock, say \$6 to \$8 in
value, were thrown aside, and it was only by con-
stantly making horn-spoon tests the grade desired
was secured. The mill has been running during the
last 10 days on paying ore from the Mescal
lode and from the old Rouse claim on the
Fort Bowie road, which seems to be a prom-
ising small vein. I regret to learn that Fowler &
McGregor talk of bidding our camp good-by.
The moving of their mill from the northern side of
the mountains to where it is now cost a round sum,
and the ores from the Philadelphia lode did not
yield up to expectations, so that they were consid-
erably out of pocket. Their claims in Park canyon
are so broken and faulted that deep tunneling alone
will make them productive, and for the present
means are not available for that work. The Casey
Bros. are getting good ore from the Juniper mine.
With their arastra at work during the summer
months they make a satisfactory living. Work has
been resumed in the Silver Cave 300-foot
tunnel, Geo. Phillips being, as in the past, S. R.
DeLong's stand-by in driving ahead. The rock in
the face is said to be very hard.

OVER THE MOUNTAINS.—At the Tevis camp all
is quiet. No work is being done on the mines or
in the mill except in making some changes in the bel-
ting. I am unable to give any reason for the cessa-
tion of work.

TO PUMP AT TOMBSTONE.—*Phoenix Gazette*,
Feb. 25: A large pumping corporation has entered
into arrangements with the Grand Central and Con-
tention mining companies of Tombstone to pump
the big mines on shares, and it is thought that active
operations will be resumed on those great bullion-
producers. It is unquestionable that these two prop-
erties, if the water could be handled, are two of the
richest mines on the continent, and the fact of satis-
factory arrangements being made will be hailed
with delight by the people of Tombstone and in fact
the whole Territory. The pumping company is to
put in large Cornish pumps and keep the water
down so that the mines can be worked, and will re-
ceive a royalty on all ores hoisted from the prop-
erties.

COLORADO.

THE CONOMARA.—*Aspen Times*, Feb. 24:
Not a little interest has been aroused in min-
ing circles by the fact that the Conomara is
shipping ore. This property is one of the fam-
ous ones of the camp, the shaft having been
driven down 1000 feet to catch the Aspen mine's ore
chute. The contact pitches very steep, but it was at
last intersected and some low-grade mineral was
found. At the 900-foot level some ore was developed,
and it is from this point that the present shipments
are being made.

PARK-REGENT.—The air drills are kept busy and
the levels are being driven forward rapidly. The
work shows ore at several points and the outlook is
very bright. Jack Lindsay now occupies the posi-
tion of superintendent.

THE LITTLE RULE.—The Little Rule is reported
to be looking far better than ever before. The ore
bodies are increasing in size as development work
progresses, and the grade of mineral also shows
improvement. The ore-bins are full, but the dan-
gerous condition of the trail interferes with the ship-
ping. A jack train was lost in a slide last week and
the greatest care will have to be exercised for some
days yet in taking pack animals to the mine.

THE NEWMAN TUNNEL.—The Newman tunnel
is now being pushed forward. The air drills were
started last week and are doing effective work.

TUNNEL VENTILATION.—The subject of tunnel
ventilation is one that has perplexed the engineers
considerably. The common plan has been to force
fresh air to the face and thus give good air to the
men at work. When air drills were introduced the
problem seemed to be solved, as the escaping air
furnished the supply that was needed. This plan
simply drove the gases back, and the trammers and
others who had to go in and out were seriously in-
convenienced. When Taylor & Brunton started the
Cowenboven tunnel they adopted a plan by which the
air, with all the foul gases, is sucked away from the
face. It is carried through a large pipe to the
mouth of the tunnel and a stream of fresh air is thus
kept moving in, the entire work being thoroughly
ventilated. The plan has worked so well that it has
attracted the attention of the contractors who are
boring the Busk-Ivanhoe tunnel on the Midland.
One of them came over last week with Chief Engi-
neer Bryant to inspect it, and determined to adopt
the system on the great railroad work.

LAKE CITY DISTRICT.—*Denver Republican*, Feb.
28: The Lake City district is slowly but surely
attaining prominence as one of the heaviest pro-
ducing districts of rich ore in the State. Constant
strikes are being made. Last week bodies of valu-
able mineral were encountered in the Cherokee, May-
flower and Pride of America, while suspended devel-
opment upon many good properties will recommence
in the spring. L. D. Hicks of St. Louis will begin
to open up the Crown Point in Sabaer basin at that
time. From the Palmetto mine large quantities of
ore are being extracted and stored for shipment.
The Broker is shipping two carloads weekly. At a
depth of 280 feet in the Cresco crosscut a heavy
body of ore has been encountered which will be pro-
spected 75 feet farther, with a view of ascertaining
whether this body is the main vein or a spar. An-
other property which promises to begin operations
in the spring is the Black Wonder M. Co. Litiga-
tion between the owners has for some time past fol-
lows suspended operations here. There is said to
be an abundance of good mineral in sight. Some
valuable development work is in progress on the
Sterling group in Cottonwood gulch. The Frank

Hough M. Co. intends to open up in the spring
with a large force. Another shaft will be sunk in
place of the old one which has become dangerous.
The Big Casino is another property that promises
to come to the front.

DAKOTA.

CALEDONIA.—*Deadwood Pioneer*, Feb. 29: At a
recent meeting of the board of directors of this com-
pany, the following officers were elected: W. F.
Goad, president; George K. Wells, vice-president;
J. B. Haggin, treasurer; Thomas J. Grier superin-
tendent. As already announced in these pages, the
mine was sold to the Homestake Mining Co., and
the new directory represents the purchasers.

D. & D. SMELTER.—Professor Franklin R. Car-
penter, general manager of the D. & D. smelter, re-
turned yesterday from a trip to Denver. The object
of his visit to Colorado was to examine the dry
smelting process of the Argo works. He has always
been in favor of the reverberatory furnaces, and his
recent visit to Argo has strengthened him in that
view. The reverberatory furnace is an English
method, while the blast furnace for smelting origi-
nated in Germany. In Montana the blast furnace is
used almost exclusively, although wherever the ideas
of English and American engineers are predominant,
the reverberatory furnace is used. In the new D. &
D. smelter the reverberatory furnace will be used.

CHLORINATION WORKS.—A gold brick, valued
at \$8700, was yesterday shipped out by Wells, Fargo
& Co. The brick was the result of two weeks' run
at the Golden Reward chlorination works.

BALD MOUNTAIN.—Superintendent Ellington
has a force of men at work on the Florence and has
encountered a large body of ore. The ore will not
average over \$20 a ton, but it is expected that it will
be richer as the body is farther penetrated.

GOLDEN WEDGE.—The Golden Reward com-
pany is taking ore from this mine and shipping it to
the chlorination works. The ore carries from \$35 to
\$40 a ton, and is one of the richest nines in the
company's group.

CARTHAGE.—Several men are working on the
Carthage mine and getting out a good quality of
ore. Shipments to Omaha will shortly begin.

IDAHO.

THE CLAYTON SMELTERS.—*Cor. Salt Lake Trib-*
une, Feb. 28: A. J. Crook, manager of the Clay-
ton (Idaho) smelters and the numerous mines be-
longing to that company, is in the city to spend two
or three days, on his way home from Omaha. He
reports the property of the company, especially their
mines, in excellent condition. Of course that coun-
try is all snowed under now, but the mines along
that portion of Salmon river are good enough to
make that a prosperous country were it supplied
with better and cheaper transportation facilities.

MONTANA.

AT BUTTE.—*Inter-Mountain*, Feb. 26: Of the
mines, all are working again as in the past, the Par-
rot having resumed Thursday, closing what had
seemed to be a shutdown for an indefinite time.
The mine is capable of supplying the smelter with
400 tons of ore every 24 hours. The smelter is sec-
ond to none in the county and the output is nearly
equal to that made by the Butte & Boston. The
Anaconda and St. Lawrence mines paid to-day and
distributed among their employees \$140,000 or over.
These mines are again working at their full capac-
ity and together with the Mountain Con. are em-
ploying more men than any similar number of the
same mines in the camp. The Lexington paid off
its bonds yesterday. This mine is pursuing the even
tenor of its way and work is progressing on the
deep levels. Ore sufficient is being taken from the
mine to keep the immense mill in continuous opera-
tion. There are only 12 men employed in the High
Ore, one of the most prominent of the Chambers
syndicate of mines. There is hardly any call for
ore from these mines until the reducing capacity of
the smelter at Anaconda is enlarged, as the output
of ore from all of these mines would simply swamp
the old works. All of the mines in the camp with
but few exceptions are running to their full capac-
ity, especially the large silver mines and mills on
the hill and to-day both are giving employment to
more practical miners than any other mining camp
in the country. The same may be said of the smelt-
ers, not one being in idleness, with the exception of
the old Bell out on the flat, a remnant of its former
greatness. Among the slag on the old dump, it is
stated, there is matte rich enough almost to make
some enterprising leaser wealthy. Very scattering
reports continually arrive from the mines situated in
the main range. The most noted of these are the
group over which C. H. Shoemaker is superintend-
ing the Homestake and the Maude S. This part
of the country is only in its infancy and by the time
another year rolls around the music of the mills will
be distinctly heard in its canyons. Of the Switzer
or Monitor little can be said, but it is understood
that the shaft in contemplation will be started just
as soon as the weather will permit and the disagree-
ment now existing in the company will have been
amicably adjusted. The mines of the Boston &
Montana Co. are in the same condition as during
last week. It is hoped that the big smelter at Great
Falls will be completed so as to accommodate the
vast number of miners that would be able to find
employment in the Moose, East and West Colusa,
Mountain View, Harris & Lloyd and the many other
valuable properties belonging to this corporation.
There are 5000 miners employed in Butte to-day.
The deepest shaft is the Lexington, which is 1448
feet. More ore is hoisted from the Parrot mine in
proportion to its machinery than from any other
mine in the camp. Sinking is progressing for the
1000 in the Mountain Consolidated.

NEW MEXICO.

COPPER.—*Sierra City Enterprise*, Feb. 28: M.
W. Neff & Co. blew in their copper smelter at the
Anson S. Mine, in Hanover Gulch, on Wednesday
evening with every prospect of a long and success-
ful run. They have on hand a large supply of coke
and smelter supplies and every available inch of
space around the mine and smelter is crowded with
ore, barely sufficient room being left for a wagon to
pull through on the road. The ore in sight in the
mine is of good quality and a large body is exposed
ready for extraction as soon as room can be made

on the dump or at the smelter. E. L. Doheny &
Co. have resumed work on the Alpha and
Omega properties of Houston and Thomas, near
Pinos Altos. Col. D. P. Casey, who has been in
charge of the Good Luck mine as foreman for
Brockman and Beall, will soon start work on his
own Little Bonanza at Cow Springs. May good
luck attend ye Kurnel. The Humboldt mill at
Shakespeare is being put in shape to commence
crushing ore. Frank Milstead is superintending the
job in person. About 15 men are employed at
Lone mountain chonding, that is, mining and as-
sorting the richest ore for shipment from the mines
of the camp, leaving large bodies of lower grade un-
touched. The ore must necessarily run very high to
pay cost of shipment and reduction at a smelter,
hundreds of miles away, and then leave a margin
for the miner, yet they are all making more than
good wages. The Colchis company's mill promises
some relief to our miners when completed, which it
is to be hoped will be very soon.

MOGOLDS.—The Little Fanny has another big
mark scored to her credit, a strike of richer ore than
heretofore discovered and in greater quantity having
been found in the lower level.

ALUMINUM CLAY.—*Salt Lake Tribune*, Feb. 26:
The question of getting clay rich enough in alum-
inum to pay for producing that metal is about to be
solved by one of the clay banks of Utah. The
Government has been testing clays, and even sent
to Canada for samples for this purpose, without
getting any very rich in aluminum. A short time
ago some parties got what they thought to be a
good article of fireclay and sent samples to the
Smithsonian Institute at Washington, and it was
found so rich in aluminum that the Government
officials want full particulars as to quantity and
location. The men who found this clay are going
to sink on it at once and do other prospect work,
and then they will be ready to let the secret of loca-
tion be known. The assay showed the highest per-
centage of aluminum ever tested in this country.

UTAH.

THE ANCHOR.—*Salt Lake Tribune*, Feb. 28:
The Anchor mine, Park City, is sending down from
105 to 110 tons of ore per day to the Union concen-
trator. They are driving the business so well that
the company does not permit a few snowslides to
stop the work, but just as soon as a slide blocks
the road men clean it out, and the heavily loaded
hobs and big teams soon pass as if all were serene.
Those Park City teamsters are not much afraid of
snow and are not frightened by snowslides.

BULLION-BECK AND CHAMPION.—C. J. Mulky
is in from the Bullion-Beck and Champion mine,
and says there was a big snow-storm over in the
Tintic country on Sunday. At the mine there are
employed about 250 men, to whom from \$22,000 to
\$23,000 per month is disbursed. Just now the
mine is not shipping much ore, because of the
prices of silver and lead, and in the past few days
the mine force has been reduced about 10 per cent,
leaving the force as named above, and there is a
probability of a further reduction if prices of silver
and lead do not rise soon.

The Mining Companies' Financial Standing.

The following is the financial standing on the first
Monday of the present month of the mining com-
panies listed on the two exchanges in this city:

COMSTOCK MINES—NEVADA.		
	Cash.	Debt.

* February expenses paid.
† Collecting assessment.
‡ Unsold bullion of the assay value of \$178,566.37 on
hand, with further shipments to arrive. There is an
overdraft at the Nevada Bank of \$104,707.09.
(A) Bullion returns for the month not all in.

MECHANICAL PROGRESS

Aluminum—Facts and Fiction.

The great advances recently made in the metallurgy of aluminum, by which the selling price of the pure metal has been reduced in six years from \$15 to \$2 per pound, or less, and that of its alloys reduced in even greater proportion, has led to an extensive use of the imagination by many newspaper writers and others, and a vast amount of misinformation concerning the metal has appeared in print. Scientific men even have been misled by the extravagant claims made for the new metal, and have allowed themselves to be quoted in a way which tends still further to mislead the general public. For instance, one of them predicts some day aluminum will revolutionize the world. It will be used in the construction of houses, thus superseding wood, stone and brick. It will take the place of iron in shipbuilding. The ocean steamer of to-day will be but a canal-boat compared with the aluminum ship that will fly as a bird over the waves.

In addition to this class of misinformation, which may innocently have been spread broadcast by enthusiasts, there have been cases of deliberate attempts to humbug the public by promoters of aluminum companies that never made a pound of aluminum.

After eliminating all the exaggeration and humbug about aluminum, there remain the facts that the metal possesses properties which make it very useful in the arts, that its use will enormously increase as it becomes better known and reduced in price, and that there are in actual existence new processes by which both the pure metal and its alloys may be made much more cheaply than they could be made five years ago. These processes are still capable of great improvement, and it is not at all improbable that five or ten years hence aluminum will be nearly as cheap as copper, and aluminum bronze as cheap as ordinary bronze.

There is no probability, however, that aluminum will ever replace steel as a material for bridges and other large structures, even if it ever should be made at as low a price as steel. In order to understand the barriers which exist against the cheap production of aluminum, it may be well to compare its processes of manufacture with the process of making pig-iron.

The Raw Material from Which Iron Is Made

Is iron ore, a chemical compound of iron and oxygen, mixed with various impurities, such as silica, alumina and lime. The iron ore is lavishly distributed over the earth's surface, and in many places its cost is merely that of digging it out of an open cut in the side of a hill. To separate the iron in the ore from its combined oxygen, we need a substance which has a greater affinity for oxygen than iron has, and this we find in the carbon of charcoal, coal or coke. With the temperature which may be obtained by the combustion of either of these fuels in an ordinary blast furnace, the iron ore is oxidized and carbonized, forming pig-iron, while the impurities above named run off in the slag. If the iron ore contains not over 30 per cent of these impurities it may be used directly in the blast furnace without concentration or any other preliminary treatment. The chief items in the cost of making pig-iron are therefore the mining of the iron ore and the coal, the quarrying of limestone for fluxing the impurities, the transportation of these materials to the furnace, the labor of charging them into the furnace, of removing the slag and the finished product, and the repairs of the plant. In favorable locations the total cost is as low as \$10 per ton at the furnace.

The Raw Material from Which Aluminum Is Made

Is also widely distributed over the earth, and consists in a chemical compound of aluminum and oxygen, with silica, iron and other substances, either in chemical combination or in admixture. A very impure ore of aluminum is ordinary clay. Purer ores are corundum and bauxite.

To separate the aluminum from its oxygen, however, is not as easy a matter as to separate the iron from iron ore. The heat of a blast furnace and the action of carbon will not do it. Some other means, therefore, must be found. Up to within the past few years metallic sodium was practically the only agent need for indirectly making this separation, the oxide being first converted into a chloride, and the chlorine then separated by the sodium; but as sodium is expensive, the cost of producing aluminum by this means was very great. Recently, however, it has been found that in the presence of carbon the heat of the electric arc was sufficient to separate aluminum and oxygen, and a process based upon this discovery has been used by the Cowles Electric Smelting Company, at Lockport, N. Y., for making aluminum alloys. It has also been found that if the pure compound of aluminum and oxygen, known as alumina, be dissolved by fusion in a bath consisting chiefly of melted fluoride of aluminum, the desired separation could be effected by electrolysis, a powerful current being required for the purpose. By this process, the Pittsburgh Reduction Company have been successful in producing nearly pure aluminum (about 98.5 per cent pure), and they are entitled to the credit of making the greatest reduction in the market price, bringing the price from \$8 down to \$2 per pound in one year, and of experimenting with the metal and making its qualities

known, so as to bring it into extensive use for a vast variety of purposes. The success of the electric method of producing aluminum has stimulated the owners of other processes to cheapen them, and means have also been found of producing sodium at lower prices than ever before, so that the sodium process is still holding its own in Europe, notwithstanding the competition of the electric processes.

In All the Aluminum Processes.

However, it is necessary to begin with a pure aluminum oxide, and as this is not found pure in nature, the impure oxide has to undergo a preliminary process of separation from its impurities. The reason this preliminary purification is necessary in the case of aluminum, while it is not in the case of iron, is that, whenever the conditions of separation of the aluminum from its combined oxygen are obtained, the same conditions will also separate the oxygen from the impurities, and the result will be not pure aluminum, but an alloy of this metal with the metallic base of the impurities. Thus, as oxide of iron is found as an impurity in native oxides of aluminum, such as bauxite or corundum, the attempt to make a product directly from such oxides by the electric arc, or by electrolysis, would result in the formation of an undesirable alloy of iron and aluminum, instead of the pure metal. The preliminary process of separation from impurities is a chemical one, and is necessarily somewhat expensive. It involves making a solution of the raw material by acids, the precipitation of the impurities from the solution, and finally the precipitation, drying and calcining of the pure alumina.

The cost of all these operations will, of course, be diminished in time, as machinery is applied to them, but it does not seem probable that these preliminary processes can be dispensed with, and hence the production of aluminum must always be much more expensive than the production of iron. It is not to be expected that any great revolution is to be made in the present methods of producing aluminum, and the cheapening of the metal in the future will likely be accomplished by the perfecting of existing methods. Moreover, it is not to be expected that any new method will be invented which is not already so covered by existing patents that it could not be used in practice without coming in conflict with them. There is, therefore, little hope that investors in new aluminum projects will ever reap any return from their investments.

The Field for Cheap Aluminum.

But if aluminum should ever be reduced in price to 10 or 15 cents a pound, as is claimed, what field is there for the metal at that price? It cannot possibly replace iron or steel as a structural metal, for even at 10 cents a pound it would be about five times as expensive per pound. If it be said that this largely offsets its being only one-third as heavy, and that the bulk of a pound is three times as great as that of a pound of steel, then it may be rejoined that it is only one-third as strong. It may replace silver, German silver, copper, tin and zinc for some of the purposes for which these metals are used, but by no means for all. It is too cheap to replace silver for coins and for high-priced tableware, but is excellent for moderate-priced wire. It will probably make a better roof than copper, tin or zinc, if it ever is as cheap as these metals, but is more fusible than copper, which makes it less useful for stoves, has less electric conductivity, making it less useful for electric wires, and thus far it has not been successfully brazed or soldered, in which respect it is inferior to nearly all other useful metals.

The Engineer, of London, expresses somewhat similar views concerning aluminum. It says: "More nonsense than enough has been talked about aluminum and its capabilities. It has served as the catchword of the ignorant enthusiast and the knavish empiric. Its wide diffusion, difficult extractibility, and remarkable properties seem to have appealed especially to that class of persons whose imaginative powers are largely in excess of their intellectual faculties, and, rushing in where angels fear to tread, they have been guilty of the wildest extravagances."

The same article gives some new facts concerning aluminum, which may eventually prove of some importance. It appears from some experiments made recently in France, that the strength of aluminum can be increased from about 25,000 pounds per square inch up to 52,000 pounds per square inch by alloying it with about six per cent of copper. The experiments were made on a small scale, however, and the same results might not be found true of large masses. It is only equal to the softest grades of steel in strength, and far below the strength of tempered steel.

The tensile strength of aluminum castings is about 15,000 to 17,000 pounds per square inch, or about the same as an ordinary quality of cast-iron. Castings hardened by drop forging have a strength of about 24,000 pounds per square inch. Rolled bars and sheets may have a strength varying from 20,000 to 32,000 pounds per square inch.

Aluminum is much weaker than the softest wrought-iron in compression, having an elastic limit under compression of only 3500 pounds per square inch when tested in short cylinders, and falling by flattening out at about 12,000 pounds. The metal is not a rigid metal, and no matter how cheaply it may in future be furnished, it would not be a safe material to use in large structures exposed to severe strains.

The most valuable properties of aluminum are its ductility under drawing processes and its non-liability to corrosion. It is insensible to a high degree of finish by polishing or burnishing. It becomes hard by working and requires frequent annealing. It melts perfectly fluid at about 1300°, but becomes granular at about 1000° F. It is most easily worked at a temperature of from 200° to 300°. It is apt to become granular and to stick to the rolls at a higher temperature.

As to the corrodibility of the metal, it is unaffected by either dry or moist air, by water, by sulphureted hydrogen or other sulphur vapors, by salt sea water, a weak solution of salt in acetic acid, or by sulphuric or nitric acids. These acids, however, rapidly act upon the metal in the presence of chlorine.

The alloys of aluminum with other metals have many valuable properties, and there are probably many other useful alloys of the metal yet to be discovered.

Aluminum has enough valuable properties, therefore, to make its cheap production a great boon to many arts and industries, but there is no ground for believing that it will "revolutionize the world."—*American Mechanist*.

SCIENTIFIC PROGRESS.

The End of the World

Of all changes, that change has most interest for us which affects our own planet, the earth. It has reached a later stage than Saturn, though not so late a stage as the moon; but only in long ages and by minute effects will further changes be noted. Ages hence it may be discovered that there is some slight change in the earth's orbit; or Mercury, yet nearer to the sun than we, may be seen to pursue a smaller orbit than now, and the terrible fact may come home to man that we are drawing nearer to the sun. Time goes on, and the tropics become too hot for existence, and colder regions find a welcome change to warmth. Age after age goes by, and the end is, visibly, no nearer; but the figures of astronomers only too surely tell their tale. In time the tropics will become an impassable desert and all the life on the globe will congregate around the poles. Spain has lost her vineyards and the Alps their snow; England is a burning desert and Greenland teems with the vegetation of the tropics; in smaller and smaller circles the inhabitants gather round the poles.

"But," to quote the words of Mr. Kelghley Miller, "the narrowed limits of the habitable earth can no longer support this vast increase of population, and famine begins to mow down its victims by millions. Now, indeed, the end of all life draws on apace. The heat and drought become more and more insupportable, rain and dew fall no longer. All springs of water fail, and the rivers dwindle down to streamlets and trickle slowly over their stony beds, and now scarcity of water is added to scarcity of food. Those who escape from the famine, perish by the drought, and those who escape the drought are reserved for a fate more awful yet. For a time the few remaining inhabitants are partially screened from the overwhelming power of the sun by a dense canopy of clouds formed by the evaporation of every lake and sea. But soon the sun scorches up these vapor banks and dissipates them into space as fast as they can form. Then the fiery orb shines out in an unutterable splendor without the slightest cloud-wreath to interpose between himself and his victims. Then the last denizens of the world are stricken down and consumed—the last traces of organic life are blotted from its surface."—*Loughman's Magazine*.

But we "won't worry about it."

Gun Cotton and How It Is Used.

Prof. Munroe recently gave before the London Institute of Boston a very interesting and instructive lecture on the manufacture, use and power of gun cotton.

The lecturer traced the experiments with the explosive from its discovery, in 1832, up to the present time, and spoke of several of the most fatal explosions which attended the experimental stage.

After experiments by Prof. Hill, of the United States torpedo station, gun cotton was adopted as an explosive for use in the navy in 1854. In preparing it for this service the gun cotton is, by successive pressings in hydraulic presses, the last of which has a pressure of 6800 pounds to the square inch, made into little blocks measuring $2\frac{1}{2}$ inches each way. It contains from 10 to 16 per cent of water, but when issued to the service contains 35 per cent. Before being made up into blocks it is carefully tested.

Prof. Munroe declared that gun cotton, correctly prepared and handled according to directions, was the safest of the explosives to use. It was dangerous only when the materials had not been thoroughly purified, or the union of acid and cotton incomplete.

In proof of what could be done with it, a picture was thrown upon the screen showing the workman cutting it with chisel, jig saw and lathe to fit it into a shell. Another illustration was the extinguishing of a block that was burning by pouring water upon it. Two thousand pounds of it had been burned in a bonfire without an explosion.

One volume of the explosive gives 829 of the gas, and the pressure developed by combustion

is 81 tons to the square inch, and by detonation is 157.5 tons, the latter being in contact however. The effect of the explosion of one particle on another is so rapid that it would take only one second for it to pass through 19,000 feet of the explosive.

It was shown by the stereopticon that the letters U. S. N., with the date of manufacture that are on the bottom of each block may be impressed upon an iron plate upon which the gun cotton may be exploded. It is a curious fact that, if the marks on the blocks are in relief, the reproduction on the iron will be raised, and, if cut in, there will be an indentation on the plate. Prof. Munroe's theory is that when the letters are cut into the explosive the gases generated in the indentations are hurled from them as a projectile from a gun. If a leaf or a delicate piece of lace be laid between the gun cotton and the iron, its impress will be left in all the perfection of outline of the original, though the article itself is absolutely annihilated.

The Artificial Production of Indigo.

Synthetic chemistry or the artificial production of materials usually found more or less perfectly developed by nature, are becoming quite common, and developing more and more the economical value to men of chemical science. Day by day, the chemist is bringing to the notice of the world more surprises in the artificial production of substances hitherto only available through the chemistry of nature.

Most of our flavoring products and many syrups and sugars are now artificially produced. A great number of artificial products, possessing valuable medicinal properties, are now to be found on the shelves of our druggists. Quite recently a compound has been artificially devised which possesses tonic properties more powerful than those of any medicine hitherto known. It is now considered within the range of early possibility that important foodstuffs may soon be obtained from the laboratories of chemists.

In the matter of the production of colors for dyeing purposes, the chemist has now so much clearer field. All he needs for his raw material is the waste from bituminous coal. Out of that black, unsavory waste he materializes nearly all the colors of the rainbow, and each in almost infinite varieties of shades.

In addition to what has long been done in this direction, the artificial production of indigo seems now in a fair way to drive the vegetable indigo products to the wall. An interesting communication upon the artificial production of indigo has recently come from Mr. I. van Levenstein, who states that "there is no difficulty whatever in carrying out this beautiful discovery, but the yields are poor in consequence of the great destruction of material before the glycerine is converted into indigo. Notwithstanding this fact, the fate of the indigo planter is still in the balance, and the danger which is ahead of him does not rest so much with the synthetical production of indigo, but must be looked for in the improvement in the production of blue coal-tar colors, which are constantly being brought out. We already possess more than one coal-tar color, which has, to some extent, taken the place of indigo, and there is not the slightest doubt that before long chemists will be successful in further improving the processes of manufacturing these blue coloring matters, which may not only possess the valuable dyeing properties of indigo, but may even surpass the latter."

Indigo has become a most important commercial product, representing an annual value of over \$20,000,000, and constantly increasing. The production of artificial dyes is confined almost exclusively to Europe. Why should not our American chemists turn their attention more closely to this industry? The field is wide and of almost indefinite value.

THEORIES OF COAL COMPOSITION.—It is now asserted that the attempt which has been made by certain eminent German chemists to connect the physical phenomenon of coking with the chemical composition of bituminous coal—especially with reference to the richness of the coal in what is called disposable hydrogen, or that proportion of it which is in excess of the quantity required to form water with the oxygen present—does not correspond with observed results. Nor, again, does the richness of a sample of coke in carbon determine its coking qualities, the fact being that two specimens of coal, of practically identical carbon composition, are often to be found to behave very differently in the retorts of coke ovens. It is, therefore, argued that, if the property of coking does not reside either in the surplus hydrogen or the fixed carbon, it is certainly not to be found in the contents of the coal in oxygen, which give no indication whatever of the physical behavior of the coal under heat. Some coking coals coke without much swelling, while others swell considerably in the process. In either case, the coal must undergo a stage of fusion, in which it becomes a thick, semi-fluid mass, through which the gas escapes. But why one kind of coal should swell considerably, while another variety of similar composition does not, is admitted to be a problem not apparently capable of solution from any of the chemical data usually preserved in analyses of coals.—*Iron, London*.

THREE NEW ASTEROIDS were discovered by European observers during the second week in February. The magnitude of one was 13, of the other two, 10.

USEFUL INFORMATION.

TATTOO MARKS CANNOT BE REMOVED.—It has often been claimed that tattoo marks may be removed by pricking over them with goat's milk. This is a mistaken idea. Chemists and others have for years experimented with various preparations in the hope of discovering some agent to wholly remove India-ink marks from the human skin. Nothing, however, has as yet been found that will remove a portion even of the objectionable marks, unless, possibly, the attempt be made immediately following the tattooing process. At Mount Washington University Hospital, Baltimore, an experiment was some years ago made in presence of the writer upon the forearm of a noted character of that city who died there. Before his death the man granted permission to the students of the university to experiment as they saw fit with his dead body. One of these students, curious to learn everything possible connected with the practice of tattooing, cut from the dead man's arm a strip of skin upon which a coat-of-arms appeared. Beneath the skin the design remained visible. By degrees the flesh was removed, the design in India ink still remaining in sight until finally the bone was reached. After a thorough sponging for the purpose of removing the blood and pieces of flesh remaining, it was found that the representation still appeared. After cutting away a small section of the bone, the India-ink mark was found to have not penetrated beyond.—*Boston Bulletin.*

SMOKE PREVENTION IN LONDON.—Considerable success is attending the experiments now being made on the Thames embankment, London, in preventing the emission of smoke from steam-making plants. The London *Engineer*, speaking of it, says: The apparatus consists of a fan which passes the products of combustion from the fire of a portable engine into a chamber partly filled with water. The products enter a horizontal perforated tube which is partly immersed in water in this chamber, and is rotated at about 200 revolutions per minute. Upon this tube are arms carrying perforated sheet iron, so that by the rotation of the tube and these arms the water is thrown up in fine spray, through which the smoke must pass on its way to an exit from the upper part of the chamber. Perforated plates are also placed in the upper part of this vessel, through which the escaping gases must pass, and which throw down the water. The high temperature of the products of combustion which enter this chamber causes the evaporation of some of the water, which passes away as vapor at atmospheric pressure. The products of combustion, or smoke, are robbed of all carbonaceous material, and, to some extent, of other deleterious constituents, including sulphur. These collect in the water and form a scum, which is constantly drawn off. It is proved that smoke can be treated in this way, and it is claimed that the cost is small enough to commend the system and apparatus.

CHITTIM BARK.—It is not generally known that quite a large business is done in some parts of Oregon in chittim bark. It is only within recent years that it became known that there is a market for this bark. It is produced in considerable quantities along many of the streams of Oregon. It grows abundantly in Benton county, especially in that portion of the county lying west of the coast mountains. The trees are stripped in spring from top to root. The bark is taken in convenient lengths for handling. After it is dried it is usually sold by its first owners in that condition. It is ground fine and enters largely into the manufacture of certain medicines. The price of the raw material varies considerably with the season. In the spring, when the market is crowded, it reaches its lowest point, and in the fall and winter usually advances. Last spring it sold in San Francisco at \$70 a ton, which was considered a very low figure.—*Oregon Paper.*

PHOTOGRAPHY AND SURGERY.—Strange as it may seem, photography has become a most valuable adjunct to surgery. Scientists have recently discovered that spasms are caused by affections of the nerve centers, and that the disturbance of a certain center is invariably followed by identically similar contortions of the muscles. Tumors on the brain are now located, according to an eminent local surgeon, by means of the instantaneous photograph. A tumor must of necessity press upon a nerve center, which causes the sufferer to be subject to violent spasmodic attacks. While in this condition he is photographed, and the exact position of the tumor discovered. Several successful experiments of this nature have been conducted, and henceforth the camera will play an important part in surgery.

INVENTIONS AND INTELLIGENCE.—The records of the Patent Office make some peculiar revelations. The annual report of the Commissioner, just issued from the Government Printing Office, shows that in a twelvemonth Massachusetts took one patent for every 573 persons of her population, while Mississippi took one for every 23,574. Connecticut is credited with one patent for every 700 of her population, and Alabama with but one for every 16,611. New York takes one for every 1185 and North Carolina one for every 19,714. Thus the figures show that the States where general intelligence most widely prevails are granted the largest number of patents.

GOOD HEALTH.

A CURIOUS CASE.—The New York Associated Press reports of Feb. 24th state that Frederick Gaedke was then dying at the Presbyterian Hospital, New York, from a disease rarely seen in this country. It is called osteomalacia, which means the complete breaking up of the entire bony structure of the body. A few evenings previous his wife lifted Gaedke in his bed. She took hold of the right thigh bone and it snapped like a pipestem close to the hip joint. Gaedke fainted from the pain and was taken to the hospital. He was recently bitten on the finger by a mouse. He caught cold and the entire band became inflamed and very painful. After while it healed apparently. Three months ago Gaedke had to take to his bed, being afflicted by what was thought to be muscular rheumatism, and his body was racked by lacerating pains and the flesh became sore. He could not be moved nor even touched without being thrown into convulsions. This condition continued for several weeks and then a slight swelling appeared in the glands of the neck. The swelling in the neck was not understood at the time, but it is now known that it was caused by the establishment of a little colony of tubercular vesicles in the glands. These little micro-organisms had doubtless originated in one of the lungs and had started from there to make the conquest of his body, finally destroying the animal matter of the bones and leaving only the mineral substance, which has rendered them chalky and extremely brittle.

COCONUT FOR TAPEWORM.—Prof. Parisi of Athens some time since called attention to the tannic properties of the coconut, when freely ingested. His attention was drawn to the subject from an accidental experience in his own case. While traveling in Abyssinia, he one day took a considerable quantity of the nut, sufficient to produce an attack of diarrhea. After awhile, much to his surprise, with one of these diarrheal motions, there came away a complete tanna, head and all, and quite dead. After his return to Athens he made some observations in this line of treatment, and reported an almost invariable success. In only one instance did he fail to secure the head. His method was to order the milk and pulp of one coconut, to be taken in the morning, fasting, no purgation or cessation from business being required. In this country Dr. Allison has reported, in the *Medical Age*, a case where the use of *Felix mas*, oil of turpentine, and chloroform had successively failed to effect a complete removal of the parasite, but in which the patient by chance partook of a coconut, and soon after was relieved of a dead tapeworm with its head. Since then he has had occasion to prescribe coconut in this trouble, and has found it the pleasantest of all the tannic acids, and one that does not require the administration of a cathartic.—*N. Y. Medical Journal.*

A CURE FOR HANG NAIL.—A small and almost imperceptible hang-nail often involves the owner of the hand which bears it an endless amount of annoyance and vexation. It is the general rule—manicures to the contrary, notwithstanding—that the nails least attended are better than those that are continually doctored. The man who cuts a hang-nail in nine cases out of ten lays the way for a much more vigorous successor. Satisfactory results are almost always obtained by pushing the skin back from the nail after washing the hands. The dry end of the towel should be taken and the skin pressed back wherever it overruns the nail. This breaks its adhesiveness to the nail and makes hang-nails impossible. Where the skin is allowed to grow fast to the nail, trouble invariably results, because the nail in growing out pulls the skin with it, and when it breaks from the tension the hang-nail is formed.—*Phila. Inquirer.*

THE EFFECT OF SUNLIGHT.—A man who has been annoyed for years by the fact that one side of his mustache grows about twice as fast as the other side claims to have found an explanation in the circumstance that he sits all day at his desk with one side of his face turned to a window, the light from which stimulates the growth of the hair on that side.

"MIRACULOUS" CURES.—The invalid girl, in a Pennsylvania town, who arose from her bed and rushed out of the house when the alarm was given that the place was on fire, simply proved the influence of mind over body. Great danger, like extreme religious enthusiasm, frequently works what have the appearance of miraculous cures, but science readily explains them.

LINSEED OIL FOR CHILBLAINS.—Mr. A. J. Arnold of Gibsonville, Idaho, in a letter to the Press, gives the following from his experience in curing chilblains: Take boiled linseed oil; warm the foot before a fire, then rub in the oil thoroughly. The pains will soon cease and if persevered in the trouble will soon entirely disappear.

SHORTHAND WRITING by machinery is as yet a novelty in Great Britain. It is, however, alleged that a new stenographic machine in use by the Italian Parliament is capable of recording 250 words a minute, and can be readily manipulated by a blind person.

ENGINEERING NOTES.

IMPROVED TRAVELING FACILITIES.—Late accounts from Russia say that the Government is pushing forward its project for a railway through Siberia. Several hundred miles of the line are already completed. But there is a very large gap to be filled, as it is nearly if not quite 4000 miles from the end of the present line to the eastern coast, where the railway is intended to terminate. Generally speaking, the country is a vast plain, and therefore an easy one for the construction of a railway. There are only two or three mountain chains in the whole distance, and these offer no more obstacles than are presented in this country by the Alleghenies and far less than those of the Rocky mountains and the Sierras. When the railway is completed so that one can travel by train from Vladivostok to St. Petersburg, the time around the world will be materially shortened. With steamers making direct connection between Vladivostok and San Francisco, the journey from New York to New York again can be made inside of 45 days, and may easily be brought down to 40 days if the steamers and trains run at fair speed, and do not keep the traveler waiting too long in the connecting ports. How the world moves! Yesterday the writer picked up a book upon California, written in 1850, in which the author said: "I venture the prediction that the time will yet come when men now living may go from New York to San Francisco in less than 30 days." I might be inclined to laugh at him, now that we have reduced the journey to 4½ days, were it not for the fact that in a book of my own, written 24 years ago, I find that I spoke of the possibility of going around the world in "scarcely more than 100 days."

A NEW PROPELLER SCREW has recently been devised by Mr. Ruble of Newark, N. J., which is being placed in a boat 100 feet long by 20 beam. The screw consists of four blades firmly riveted to a buoyant and air-tight cylinder of boiler iron having conical ends. Two of these screws, each six feet in diameter, will propel the new boat, Mr. Ruble thinks, at the rate of 23 miles an hour. The peculiarity of this form of screw is that it is not intended for total submergence, but will lie partly above the surface, one-half to two-thirds being submerged. The inventor says his wheel, running in this manner, will not churn, and will move with the slightest degree of slip while applying the full energy to be developed from a wheel of a given diameter and doing it with one-fifth of the power needed to run an ordinary screw. Owners of steam launches, tug-boats and other screw-propelled craft are watching the progress of the work on the new boat, and waiting for the trial which will take place on the Passaic next month. Mr. Ruble is very confident of success with his new propeller, claiming that he has already met with the most satisfactory experiments on a small scale.

A GREAT BRIDGE.—The great steel bridge across the Columbia river at Vancouver will be a mammoth concern. It will be 6000 feet from the Washington to the Oregon shore; it will be double-tracked with roadway on top for teams, and will be erected upon pneumatic piers. The pivotal pier, or draw pier, will support a draw which will give an opening of 200 feet space on either side for vessels to pass, and the span immediately south of the draw span will be 375 feet. Whole structure to be of steel, built 10 feet above the high water of 1876, and 40 feet above low water. On account of the sandy formation it will be necessary to go down 80 feet below low water to get a firm foundation. This gigantic structure will cost over \$1,000,000. It will be Jan. 1, 1892, before the cars can pass over it. The company is pushing the bridge and also the road as fast as men and money and their present perfected plans will permit.

NINETY FOUR MILES AN HOUR.—Charles Watts, superintendent of the Chicago division of the Pittsburg, Fort Wayne & Chicago road, claims that the fastest time ever made on an American railway was over that road lately. His official report showed that this special train ran 53 miles in 45 minutes, 11 miles of which were covered in seven minutes, or at an average speed of 94 miles an hour. The train sheets show that the above statement is correct.—*St. Louis paper, Feb. 9.*

EXPERIMENTS are now in progress to test the geological structure of the sea bed upon which it is proposed to construct the bridge across the English channel. Examinations of the French coast have been finished, and so far as they have proceeded on the English side of the channel the results have been highly satisfactory, the sea bottom being very solid and suitable for the proposed structure.

THE GREAT BROOKLYN BRIDGE is a success far beyond what was ever expected of it. The trustees are now pushing the plans lately adopted for the issuance of \$1,500,000 bonds for the improvement in the carrying capacity of the bridge, and \$1,000,000 bonds for the approaches.

THE GREATEST DISTANCE recorded at which the sound of cannon has been heard was on the 4th of December, 1832, when the cannon of Antwerp were heard in the Erz-Gebirge mountains, at a distance of 370 miles.

ELECTRICITY.

EARLY INSULATION OF ELECTRIC WIRES.—Mr. Davenport, a Vermont blacksmith, is said to have been the first person to conceive the idea of an electric motor. His idea first began to take shape some 50 years ago, according to the authority of Mr. F. L. Pope, in the *Electrical Engineer*. While at work upon his invention he found it necessary to insulate his wires. Being poor and almost without means, his wife gave him her wedding dress as a thing less needed than anything else, which he tore into strips and wound about his wires. This first effort at insulation was followed soon afterward by an employe of Morse who found it necessary to insulate the wires of his pioneer telegraph between Washington and Baltimore. To do so he employed several men to start out from Washington with brushes and tar-buckets to cover the wires with tar. They had a hard job of it and met with much wonderment and no little jeering. No "tavern" on the route would give them and their tar-buckets any hospitality, and the men were obliged to secure food and lodging as best they could as they worked slowly over the route. That was in 1846. Later, waxed cloth was used to insulate at the point where the wires met the suspension pins. The only result of that trial was that the bees from all the country round made a dead set at the waxed rags, and in a short time were reveling in a beeswax boom that seemed without end. Their millennium came to an untimely close with the October frosts, and waxed rag insulation of that kind passed into history.

PHONOGRAPHY VS. STENOGRAPHY.—Short-hand writing, says London *Colonies and India*, will soon be a thing of the past. Heads of firms and confidential clerks now talk their letters to the phonograph, which dictates them to the typewriter. The waxen cylinders can be stored away, and are more reliable in case of dispute than shorthand notes. Indeed, it will not be long before the phonograph pushes stenography completely in the background. The reporter stood a few yards from the speakers and repeated the speeches into one of the machines until the cylinder was covered by the mystic indentations. Then the operator turned to the other machine and talked into that while the first cylinder was removed and placed in the bands of the typewriter.

AN ELECTRIC TRICYCLE.—There is now being perfected in Boston, an electric tricycle which promises great things. The tricycle is made possible by a recently invented motor, which, weight for weight and bulk for bulk, is said to be about twice as powerful as those of the old models. The machine has now reached a point where it can be run for a distance of from 50 to 60 miles without the storage battery, which furnishes the current, being recharged. Those interested confidently predict that when the machine is placed upon the market it will be provided with a battery powerful enough to propel the machine for a distance of at least 100 miles. The tricycle, it is said, will be offered to the public next spring.

ELECTRIC ROADS.—The San Francisco & San Mateo railway company has been incorporated to build an electric road along the route of the franchises granted to B. Joet et al. by San Francisco and San Mateo counties. The capital stock is \$2,000,000, of which \$40,000 have been paid up. The Governor has signed what is known as the "Electric Motor Bill," making the use of electric motors on city roads lawful, and granting that street railway lines may be operated for a distance of four blocks on the same thoroughfare.

ELECTRICITY IN FARMING.—The idea of utilizing electricity for the fertilization of land is not by any means new, but it has been reserved for Spain to inaugurate a new use of the electric motor in plowing land. Such a plant has been set up on the property of the Marquis de la Laguna. A water-wheel of about twenty-horse power will be used for the generation of the current, and the plow will be worked at a distance of three miles from the generating dynamo.

ELECTRIC VS. CABLE.—It is stated that there are now in operation in the United States 260 miles of electric street railroads, which is five miles more than is operated by cables. There are five different systems of electric roads now in operation—the Thomson-Houston, the Sprague or Edison, the Short, the Westinghouse and the Roe.

A NEW ELECTRIC WELDING SYSTEM.—It is said that M. Paul Hobo and a M. Lagrange, an officer in the engineers, have devised a system of electric welding which is essentially different, so it is stated, from that of Elihu Thomson. The Hobo-Lagrange process will be worked in Belgium by the Julien company.

LIGHTNING.—Prof. Bidwell, writing in *Nature* of lightning, quotes figures showing that in England and Wales, from 1852 to 1880, the average annual death rate from lightning was considerably below one per million of the population.

ENGLISH ELECTRIC COMPANIES.—During the year 1890 more than 120 new companies connected with electrical engineering were registered in England, the total capitalization being upward of \$65,000,000.

Passing Events.

The late heavy fall of snow in the Sierra Nevada mountains insures a good milling stage of water in the Carson river all summer. On this side of the range, too, there will be plenty of water for the quartz and drift mines of the mountain counties.

The floods in Arizona have been very disastrous. At Yuma some 1500 people are homeless. The Gila and Colorado rivers have both overflowed their banks. In other parts of the Territory much damage has also been done. In the southern portion of this State bridges have been washed away and some property destroyed. The railroad companies have been the heaviest losers.

In the death of Senator Hearst California loses one of her most prominent pioneer miners. This gentleman was a legitimate miner rather than mining-stock dealer, and has developed properties all over the coast, employing many hundreds of men and amassing a very large fortune from his mining investments.

The outlook for the mining season is excellent and the probabilities are that California will increase her gold product this year in view of the many old quartz properties being reopened and the increased interest in drift mining.

The Idaho Mining Company of Grass Valley has declared dividend No. 251 of \$2.50 per share, which amounts to \$7,750.

Production of Precious Metals—1890.

Edward O. Leech, the Director of the Mint, has submitted to Congress a report on the production of the precious metals for the calendar year 1890.

The gold product of the United States was 1,588,880 fine ounces (Troy), of the value of \$32,345,000, an increase of \$45,000 over the product of the preceding year.

The silver product of our own mines approximated 54,500,000 ounces, corresponding, at the average price of silver during the year, to \$57,225,000, and at the coining value of silver, to \$70,464,645, against a product of 50,000,000 fine ounces of the commercial value of \$46,750,000, and coining value of \$64,464,464, in the preceding year, an increase of 4,500,000 ounces in the silver product of the United States last year.

The silver product of our smelters and refineries was 64,920,927 fine ounces.

The total value of the gold deposited at the Mints during the calendar year was \$56,217,105.82, of which \$31,234,342.60 was domestic bullion, \$4,352,422.70 foreign gold bullion, \$8,857,447.61 foreign gold coin, \$558,386.85 light-weight domestic gold coins, \$3,765,364.28 old jewelry, plate, etc., and \$7,449,141.78 re-deposits.

The coinage executed during the last calendar year was the largest in the history of the Mint service, aggregating 124,025,365 pieces of the value of \$61,054,882.84.

The total gold imports were \$20,379,456. Exports, \$24,095,163, a net loss of \$3,715,712.

The total silver imports aggregated \$30,782,531. Exports, \$26,614,003, a gain of silver of \$4,168,528.

The lead ores imported into the United States contained 36,231,731 pounds of metallic lead and \$7,252,442 in silver.

The amount of precious metals used in the arts in the United States during the calendar year was—gold, \$18,105,901; silver, \$9,231,178, of which \$10,717,472 gold, and \$7,143,635 silver, was new bullion.

The metallic stock of the United States was approximately, on January 1, 1891:

Gold.....	\$704,597,123
Silver.....	486,545,074
Total.....	\$1,191,142,204

Owing to the brief time since the close of the last calendar year, statistics of the product of gold and silver in the world, by producing countries, for the calendar year 1890 are not complete.

Complete returns, however, have been received from Russia, Australasia, South Africa, British India, Venezuela and a few other countries based upon which the Director estimates, as a mere approximation, that the gold product of the world for the calendar year 1890 was \$118,490,000, a falling off of \$3,007,000 from 1889; and that the silver product of the world was 130,650,000 fine ounces, an increase of 7,859,375 fine ounces over 1889.

The report is replete with valuable statistics on the production, coinage and movement of the precious metals throughout the world.

The Course of Silver.

There was a marked improvement in the price of silver during the past calendar year, the price reaching the highest point in 12 years. The fluctuations covered a range of 26 per cent, a wider range by far, than in any previous year. At the commencement of the year, silver was quoted at \$0.96 per fine ounce. It reached \$1.21 on August 19, and closed on December 31 at \$1.04½.

The average price during the year was, in London \$1.04½; in New York, \$1.05.

At the lowest price reached during the year the value of the silver contained in the silver dollar was \$0.74½; at the highest price \$0.92½; the average price \$0.80½. The shipments of silver to India, China and the Straits from London amounted to \$41,398,000 during the year. The amount of Indian Council Bills sold aggregated \$76,890,000.

The imports of silver aggregated \$30,782,531. Exports, \$26,614,003, a gain of silver of \$4,168,528. During last year we used \$9,231,178 silver in the arts, of which \$7,143,635 was new bullion. The stock of silver in the United States on Jan. 1st last was \$486,545,076. The United States Mint coined last year \$38,043,004 in silver dollars, and \$1,159,904.20 in sub-

siary coin. The Mint also manufactured silver bars of a value of \$9,094,592.54.

The total amount of silver offered for sale to the Government during the year was 68,130,457 fine ounces, and the amount purchased 37,594,373.75 fine ounces, costing \$39,991,840.80, the average cost being \$1.06 per fine ounce.

The Late Senator Hearst.

After a long illness, Senator George Hearst of California died at his residence in Washington on Saturday night. Senator Hearst was well and favorably known to the mining community of this coast, he having been closely identified with the mining interests since the pioneer days of this State. He was placer-mining at Placerville, El Dorado county, as early as 1850, and the quartz-mill he erected was among the first built and operated in California. He was in Nevada county when the Washoe excitement broke out, and his party, including Melville Attwood, Judge Walsh and A. E. Head, was the second to arrive there from California. He obtained interests in the lode which proved profitable, and he also was successful in mining ventures in Pioche and in Eureka. Mr. Hearst had his ups and downs financially for some years, and in 1872 joined J. B. Haggin in the purchase of the famous Ontario mine of Utah, which has yielded \$23,000,000 of silver and paid \$11,000,000 in dividends. The Daly mine, another dividend-paying property, was also purchased, and these two mines laid the foundation of Mr. Hearst's large fortune. Messrs. Haggin and Hearst next purchased the Homestake mine on the Black Hills of Dakota, where they put up one of the largest mills in the United States. This mine has also paid handsomely.

The most important mining purchases made by Mr. Hearst and his partner was the world-famous Anaconda copper mine, Montana. This mine has a plant which is valued at some \$5,000,000, and has paid its owners immense sums of money in dividends. The output is larger than that of any other copper mine in the world.

Mr. Hearst has made many other investments in mines in about all of the Pacific Coast States and Territories. He has also made large investments in land in California, New Mexico and Mexico.

Mr. Hearst never took the management of any one mine, and made few locations of his own. But he was always ready to purchase and to sell. Messrs. Hearst and Haggin were very successful in mining, and adopted two rules to which they rigidly adhered. In the first place, they never bought interests in a mine, nor shares in properties which were controlled by others. When they purchased, they purchased the whole, kept it, and managed it themselves. Occasionally they sold an interest, or a few shares, to their superintendents or the public, but they kept the control in their own hands.

Secondly, Mr. Hearst was never willing to give for a mine more than the value of the ore that was in sight. When owners, seeking to sell, urged that the invisible supply of ore was probably larger than the ore in sight, and should be considered in the purchase-money, Mr. Hearst would reply: "That's why we are willing to buy. If there is no more ore in your mine than I can see, we shall make a bad bargain in paying you the value of that visible ore for the property." When the owner retorted that if he was to get no more for his mine than he could see in it, he had better keep it and work it himself, Mr. Hearst would bid him do so. "We," he would say, "are not hankering after your mine. We think well enough of it to give you in cash down the money which you can take out of it in three or four years' work. We look to the invisible supply for our profit. But we haven't the least objection to your taking both the visible and invisible supply. We can find other uses for our money."

Mr. Hearst was a very plain man and his wealth did not in the least change his character. He was always approachable and always charitable. Many an old prospector or miner, or old pioneer "down on his luck," has had cause to thank him. The phrase of "honest miner" was aptly applied to him, for it has been truly said the accumulation of his fortune was not in any way due to the losses of others. He was not a stock-dealer, but made his fortune by legitimate investments in mines and their practical development.

Silver Legislation.

Congress adjourned on Wednesday of the present week without further legislation on silver. There is no denying that metallists were sanguine of passing a free-coinage bill up to the time when ex-President Cleveland wrote his short but pointed letter taking grounds against unlimited coinage of silver by this country. With the ex-President's stand against unlimited coinage of silver, under the belief that the time is not ripe for such a measure, leading bimetallics evidently did not make much of an effort to promote further legislation by this Congress, well knowing that the next Congress is pledged to free coinage, and if President Harrison vetoes a free-coinage bill they will have a sufficient majority in both houses to pass the bill over his head. Indeed, several leading bimetallic papers at the West were outspoken in advising that legislation be not forced this session, claiming that with the Grange, Farmers' Alliance and Knights of Labor working in harmony to secure the free coinage of silver, large numbers are being proselytized, which will bring about the early consummation of their efforts in that direction.

Events within the past two months have, outside of Congressional legislation, put an entirely different phase on the silver situation. The present output of the mines in this country is claimed by well-informed parties to be not more than, if as much as, the Government's monthly purchases, and with our product being cared for by the Government, foreign buyers will soon absorb the available surplus of the world, besides taking the output of other silver-producing countries. Already free buying by India, China and Japan is setting in, while two other nations are quietly securing round procons. It is said, in well-informed financial circles, that foreign purchases this spring will be unusually heavy and in consequence prices will steadily advance.

In this city, the first time since May, 1890, foreign buyers are in the market for silver bullion. India and China have agents here securing all they can at reasonable figures—even paying an advance over Mint quotations. It is also said that there is a speculative inquiry for silver coming from parties who believe in much higher prices.

Bearing on the present status of the market, we give the following from the New York *Tribune* of Feb. 26th:

The silver pool in New York is reported to have lost heavily from the collapse of the Anti-Free Coinage bill in Congress. At the outset of the scheme silver jumped up rapidly until it was quoted at \$1.21½ per ounce, and the metal was expected to rise to \$1.29, equal to a dollar in gold. At length silver was stored in New York to the extent of about 10,000,000 ounces, including 7,333,000 in the vaults of the Mercantile Safe Deposit Co. It is said that the average cost to the speculators has been about \$1.10 an ounce. To prevent importations, they have been compelled to keep the Government supplied, and their sales have realized, on an average, only about \$1.05 an ounce. They are, therefore, out five cents an ounce on their transactions, or say \$2,500,000, including storage charges and interest.

The above indicates that the big bugaboo of large holdings at the East has dwindled, under selling, to very small proportions.

SILVER MINES BOUGHT.—It is announced at Chicago that papers have just been signed for the transfer of the silver mines known as Badger, Porcupine and West End, located at Port Arthur, Ontario, to Herbert M. Nichols of Denver, who is said to be acting for a syndicate composed of Englishmen and Americans. The single sale, it is said, aggregates an amount approximating \$10,000,000. These three mines produce one-half the silver taken from the Port Arthur district. The operations of this syndicate are the direct result, it is said, of the silver legislation in the United States, and negotiations, it is claimed, are now under way for some important mining properties in Old Mexico and Colorado.

THE Legislature has made an appropriation of \$20,000 to fit up and preserve the old Sutter Fort, which stands in the city of Sacramento, between Twenty-sixth, Twenty-seventh, K and L streets. The Native Sons were two years in raising \$50,000 to buy the property, which they gave to the State.

MR. MCARTHUR, the inventor of the metallurgical process which bears his name, is expected shortly at Baker City, Oregon, and will superintend the tests of the process to be made at the Eureka and Exelsior mines at Crocker Creek.

Amalgamation at the Comstock Lode.

A Historical Sketch of Milling Operations at Washoe and an Account of the Treatment of Tailings.

NUMBER IV.

[By A. D. Hobbs, Jr. Read before the American Institute of Mining Engineers.]

XI. Treatment of Tailings at the Lyon Mill.

The plant of the Lyon mill was slowly wrought out by experience. The original mill had 30 stamps, 20 Wheeler pans, 10 settlers, and 3 "lavaderos" or washing-tubs. The power was furnished by a 50 foot overshot water-wheel. The pans first used for tailings held 1500 to 1800 pounds to the charge. When the Andrews reservoir was bought, in 1869, 20 Wheeler pans and 10 settlers were added, each pan holding charges of 2500 to 2800 pounds. In 1870 and 1871 very large pans for tailings came into vogue. These were "combination" pans, with iron bottoms and wooden sides. Janin was using McCone pans, which held 2 to 2½ tons of tailings (or 1½ to 1½ tons of pure slime), and Parke was introducing much larger sizes. Influenced by the reports of improved results obtained with the largest pans, the management, in 1872, took out 20 Wheeler pans, substituting two 10-ton pans of the Parke pattern, with 2 large settlers. These pans were 9 or 10 feet in diameter by about 6 feet high, and the settlers were about 12 feet in diameter by 8 feet high. Their use was attended by such a large loss of quicksilver and low yield, that they were soon thrown out, and the mill was run with the remaining 20 Wheeler pans. Finally these last were replaced by 8 combination pans of about three

tons capacity, for tailings, and 2 somewhat smaller pans for slimes, each pan being provided with a settler. The experience of the Lyon mill indicates strongly that for the material worked there, the best results are to be obtained within the limits of two-ton and three-ton charges.

The perfected arrangement of the mill was as follows:

The mill building was located on a steep side-hill with abundance of fall. The tailings were hauled from the dumps and reservoirs in cars which entered on the upper floor directly over the bins. These cars had sheet-iron hodies

supported on four-wheel trucks, modeled after the ordinary railroad pattern. They held 3300 pounds of pan-tailings, dry weight, and dumped through the bottom of the body and between the rails. The track was of railroad iron, much of it old 65-pound iron rails, bought from the Virginia & Truckee Railroad Company

when this road substituted steel rails. Care was taken to have a solid track and well-constructed rolling-gear, and hence the repairs were only nominal and the expense of handling was light.

The bins held enough to supply the mill for several days. Their spouts discharged directly into the pans.

There were eight pans for treating the tailings caught in the company's reservoirs and locally called "sand," by which term they will be designated hereafter in this paper, and two pans for the slimes, which were all purchased from other mills. The pans were supported on an open framework, admitting light and giving free access to the shafting and gearing below.

There was a settler to each pan. The sand-settlers were 9 feet in diameter by 7 feet high. The slime-settlers were 8 feet in diameter. The settlers discharged over blanket sluices which extended from the mill to the Carson river.

Besides the apparatus named, the mill contained a small boiler for heating the pans with live steam; a Chili mill for grinding copper ore and another for crushing the roasted bullion from the refinery; an extra pan or two for treating sweeps and sulphurets, and a special dissolving tub for making bluestone-solution. All the machinery was run by a Lefel turbine, placed with its axle horizontal, under a 52-foot head.

The construction of the pans is shown in the accompanying sketches, the dimensions given being those of the larger pans. Concerning the details of construction, the following points may be noted:

The height of the flanges of the pan-bottom was gradually increased until it reached the figures given. This prevented all leakage of quicksilver between the staves and the iron—a leakage which occurred, to a greater or less extent, with low flanges, despite all methods of caulking which could be devised.

Iron rings were used to protect the flanges. The greatest wear on the pan was at the discharge-hole, where, in the older construction, the iron was rapidly destroyed until the hole became enlarged to such an extent that it could no longer be plugged securely; and thus the whole bottom was, of necessity, thrown away, although sound in all other respects. By casting the bottom with an outside boss at this place, having a square socket on the inside, 7½ inches wide by 5½ inches high by 2 inches deep, this socket being filled with an oaken plug bored for the discharge-hole, and by using false bottoms, the life of the pan was prolonged for years. An oak plug lasted as long as three false bottoms and rings. A false bottom 1½ inches thick wore out a 2-inch ring and a muller.

The wooden staves forming the pan-sides were protected by a lining of inch-stuff, 2 feet long, nailed on the inside. Instead of wings, five pieces of timber, 3 inches by 4 inches by 2½ feet long, spiked vertically to the sides, were used with satisfactory results.

The muller and shoes were cast in one piece, as shown in Fig. 4. This simple form was adopted after trial of many varieties. By leaving ample spaces, both on the outside and the inside of the muller, with a proper speed, there was no difficulty in securing a good circulation of the pulp.

Besides the usual appendages of retort-house, blacksmith-shop, carpenter-shop, etc., the mill was provided with a bullion-refinery (which has been described in a previous volume of these Transactions), with sulphuric-acid chambers, and with bluestone works. Moreover, at one time there was a borax-factory attached, which was a short-lived affair. This last was in operation in 1872, when the borax excitement raged in California and Nevada. The managers of the company were attacked by the fever, and by their order a couple of dissolving-tubs with crystallizing-vats were put up in the mill. Borate of lime was hauled some 60 miles, in wagons, from Rhode's marsh, near Columbus, Nevada, and treated with carbonate of soda (also hauled a long distance) and steam. The borax produced was of the finest quality. A considerable amount was shipped to England and there sold at the highest market prices. But the price of borax fell from 36 to 8 cents per pound (local quotations); and as the latter sum was insufficient to pay expenses of manufacture at such a point as Dayton, which was far removed from the deposits, the borax department was closed.

The acid factory held two lead chambers, one 15 feet high by 20 feet wide by 45 feet long, the other of the same height and width, but 90 feet long; besides concentrating pans, where acid of 62 degrees B. was made for sale. The two chambers were run, either separately or (by preference when business demands permitted) as a system. They produced chamber acid of 45° to 48° B., and tower acid of 12° to 18° B., the latter article coming from the "bambaroon towers," which were cheap local substitutes for the more expensive Gay-Lussac apparatus. The raw materials used were Japanese or Nevada sulphur and nitre. Owing principally to the uncertain and fluctuating nature of the market, which, for a couple of months, would demand an immediate supply that taxed the extreme capacity of the works, and then suddenly fell off to almost nothing, it was impossible to run the chambers continuously, and therefore to the best advantage. Nevertheless good results were often made, in one instance, in 1877, the chambers producing 2904 pounds of monohydrated acid per 100 pounds of sulphur

(Continued on page 157.)

THE TECHNICAL WORKS

—OF—
CHARLES T. DAVIS.

A Practical Treatise on the Manufacture of Bricks, Tiles, Terra-Cotta, etc.—Including Hand Made, Dry Clay, Tempered Clay, Soft Mud, and Stiff Clay Bricks, also Front, Hand Pressed, Steam Pressed, Re-Pressed, Ornamentally Shaped and Enamelled Bricks, Drain Tiles, Straight and Curved Sewer and Water Pipes, Fire Bricks, Fire Bricks, Glass Pots, Terra-Cotta, Roofing Tiles, Flooring Tiles, Art Tiles, Mosaic Plates, and Imitation of Intarsia or Inlaid Surfaces, together with Enamelling in Polychrome Colors, Composition and Application of Glazes, etc., including Full Detailed Descriptions of the Most Modern Machines, Tools, Kilns, and Kiln Roofs used. By Charles Thomas Davis. Second Edition. Thoroughly Revised. 217 engravings, 500 pages. 8vo. Price.....\$5.00

A Treatise on Steam Boiler Incrustation, and Methods for Preventing Corrosion and the Formation of Scale. By Charles T. Davis. Illustrated by 65 engravings. 141 pages. 8vo. Price.....\$1.50

The Manufacture of Leather.—Being a description of all the Processes for the Tanning, Tawing, Currying, Finishing, and Dyeing of every kind of Leather, including the various Raw Materials and the Methods for Determining their Values, the Tools, Machines, and all Details of Importance connected with an Intelligent and Profitable Prosecution of the Art, with Special Reference to the Best American Practice. By Charles Thomas Davis. Illustrated by 322 Engravings and 12 Samples of Dyed Leathers. 824 pages. 8vo. Price.....\$10.00

The Manufacture of Paper.—Being a description of the various Processes for the Fabrication, Coloring, and Finishing of every kind of Paper, including the different Raw Materials and the Methods for Determining their Values, the Tools, Machines, and Practical Details. By Charles Thomas Davis. Illustrated by 180 engravings. 608 pages. 8vo. Price.....\$6.00

MARKET REPORTS.

Local Markets.

SAN FRANCISCO, March 5, 1891.

Continued rains, causing high waters and had made in the interior, have restricted general trade; but when the spring business opens it is claimed that there will be a large increase in the volume of goods going out on orders. Everything points to a bright future, while a fair deposit of snow on the mountain ranges insures a prosperous mining season. Next week the local money market ought to be better than for some months past. Among ironworkers the same hopeful feeling heretofore noted still manifested regarding future prospects. The decline in coal and iron is in their favor.

MEXICAN DOLLARS—The market is dull but fairly steady at about 78 1/2c.

QUICKSILVER—Receipts the past week aggregate 265 flasks, and exports by sea 35 flasks to Japan. The market is flat at lower prices. Buyers continue to haggle over prices, trying to secure better concessions in all conceivable ways.

SILVER—Department purchases in this month reported as follows:

	Offered ounces.	Purchased ounces.	Price paid per ounce.
March 2.....	7,480,000	105,000	\$ 9250 to \$
March 4.....	745,000	93,600	to \$9750

Now that Congress has adjourned, it would be in the natural order of things to send the silver market at the East to a higher range of values. There is no doubt that strong parties at the East have been quietly buying all the available surplus stock of silver to be had in the home and foreign markets. Several lines of securities abroad, whose market values are based on that of silver, have also been taken comparatively low prices. The output of the mine this country is reported in well-informed quarters to be less than one year ago. The silver situation is largely upon in our editorial department. Three foreign buyers are in the market.

BORAX—Receipts the past week aggregate 77 cwt., and exports by sea 207 cwt. to New York. The local market is steady at full prices. At the East the market is reported strong at slightly higher prices, under a temporary scarcity.

LIME—Receipts the past week show a decided decline off, aggregating only 1775 hhls. Exports by sea were only 50 hhls, and they were sent to Central America. The local demand is light, owing to favorable weather.

LEAD—The market has a steadier tone. It looks as if the market will do better, now that no fear any be entertained of Congress legislating in favor of Mexican ore.

IRON—Imports of pig the past week aggregate follows: New York, 150 tons; England, 500, total, 650 tons. The market is fairly steady around 10 quotations. Continued rains in the valleys and snowfall in the mountains strengthen the conviction that this year will witness a prosperous season among iron works.

TIN—Imports of plate the past week aggregate 805 boxes. The market for both pig and plate is fairly strong, with canners large consumers, English cables report outside holders of plate making concessions to induce buying, but makers being sold ahead, are not in the market as sellers.

COPPER—New York advices report heavy shipments to Europe. These purchases are said to have been made from outside holders. Home consumers are still restricting their buying, which allows the output of the mines to increase. A London telegram to the *Iron Age* says: Copper has undergone very little change, but the market is firmer. Sellers are reserved in their offerings, and speculative interest is rather more active. Higher prices are expected, as there is less American selling, consumers are buying moderately, but there is more inquiry from some quarters.

COKE—Imports the past week aggregate as follows: Newcastle (England), 1616 tons; Swansea, 1600 tons; Greenock, 1903. Total, 3534 tons. The market is barely steady at quotations. From the ship's side in round parcels, our quotations can be shaded from \$2 to \$3 a ton.

COAL—Imports the past week aggregate as follows: New York, 105 tons; Philadelphia, 250; Tacoma, 5900; Swansea, 882; Departure Bay, 2350; Seattle, 1450; Coos Bay, 200; Nanaimo, 3487; Newcastle, N. S. W., 2196; Port Antonio, 2180. Total, 13,345 tons. Continued free imports of coals have retarded further demoralization in the market for coal and near-by cargoes. Large consumers are well supplied, while the yards are filling up. Correct quotations are hard to secure at this writing. Our Puget Sound advices report still heavier deliveries at the water fronts for shipment to San Francisco. These free shipments, when afloat, are not calculated to improve the situation. The weather is still favorable for growing crops, which will undoubtedly cause more deep-sea vessels to come to this port with coal for outward cargoes of wheat.

Eastern Metal Markets.

By Telegraph.

New York, March 5.—The following are the closing prices the past week:

	Silver in Silver	Copper.	Lead.	Tin.
Thursday.....	97	14 25	4 30	19 85
Friday.....	97	14 25	4 30	19 85
Saturday.....	97 1/2	14 25	4 30	19 85
Sunday.....	97 1/2	14 25	4 30	19 85
Monday.....	98	14 25	4 32 1/2	19 85
Tuesday.....	98	14 25	4 35	19 85

Lead has been dull here in New York and considerable has been offered at 4.30c. Holders are afraid of Mexican being admitted by some legislative device or other. It is a bugaboo that keeps them awake at nights. Spelter is being sold at 5@5.10c. Copper has been in better demand at some reduction in price, lake being quoted at 13c. Arizona firm at 13 1/2c, casting brands, 11 1/2@11 3/4c. Very large exports of copper are being made from this country.

LA GRIFFE has attacked many miners in Arizona and Nevada, in some cases reducing the price, so the works had to be temporarily closed down.

List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific Coast.

FOR WEEK ENDING FEB. 24, 1891.

 446,905.—CABLE RAILWAY—Watriss & Kaighin, S. F.
 446,939.—METALLIC LATH MACHINE—J. Weichart, S. F.

The following brief list by telegram, for March 3d, will appear more complete on receipt of mail advices:

California—Charles H. Benoit and A. Pillot, San Jose, window screen; Luther H. Buchanan, Pasadena, assignor of one-half to J. D. Shorh, San Gabriel, electric arc lamp; John A. Buffer, San Francisco, ice-cream freezer. Washington—George W. Ansley and J. H. Boyd, Medical Lake, said Boyd assignor to said Ansley, clothes drier; Robert McMahon, assignor of one-half to Gaston, Seattle, car coupling.

NOTE.—Copies of U. S. and Foreign patents furnished by Dewey & Co., in the shortest time possible (by mail or telegraphic order). American and Foreign patents obtained, and general patent business for Pacific Coast inventors transacted with perfect security, at reasonable rates, and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

GATE.—John F. A. Millerick, S. F. No. 447,013, Dated Feb. 24, 1891. This invention relates to that class of gates adapted to be opened and closed by the wheels of approaching and receding vehicle running down cranks in the roadway. The invention consists in certain novel constructions and combinations. The object is to provide an effective and readily-operating gate of this class.

PERCH FOR BIRO-CAGES.—John F. Sweeney, S. F. No. 447,066. Dated Feb. 24, 1891. These perches are so arranged as not to extend more than half-way across the cage and are adjustable up or down. By the construction adopted, the perches are easily supported within the cage, and in proper positions with relation to each other, so that the bird can easily fly from one perch to the other without danger of breaking or damaging his feathers, and no perch need be placed over another so as to become soiled and dirty. On that portion of the perch nearest to the side of the cage is fixed, by means of fish-glue, a compound of sharp sand and red pepper. This gives an opportunity for the bird to rub and scratch itself. The pepper acts to keep it clear of vermin, and the sharp sand will wear upon the ends of the toe nails so as to prevent them from becoming too long, which is the great difficulty where birds are confined in cages.

Mining Share Market.

Although the market dragged throughout the past week, yet an undercurrent of strength was perceptible, which looks well for a higher range of values. This journal has been a consistent bull on the market from the time Con. Virginia touched \$2.50 a share, and the writer sees nothing, as yet, to warrant taking a different view of the situation, but perceives many things to justify a continuance in the same course. Since about the middle of last November, the local money market has been close, with more or less feverishness reported; but now the indications point to a healthy, easy market at an early day. During the above time, assessments have followed assessments, with more still to come. This has caused large quantities of shares held by outsiders to be thrown on the market, which were absorbed in a quiet, mysterious manner, but not by other outsiders, who have not been generally encouraged to buy, for they have been frightened by sedulously circulated bear points, and also by doubts thrown upon well-authenticated advices of important improvements in the mines. It is thought that the situation of the mining share market and the condition of the mines warrant still higher prices, which are bound to come before long, but what the manipulations will be in the interim, of course one cannot say.

The share market opened this (Thursday) morning dull and weak. After Call under systematic cross-orders, prices shaded off still more. Outside operators will do well if they enter the market now, for there is undoubtedly quite an up move near at hand.

From the Comstock mines our advices report that they are in rich ore on four levels in Con. Virginia, as they are in the upraise from the 1200-foot level. The battery assays continue to increase in value. In Andes they are running for the ore lying toward the old Burning Moscow ground. It is said to be rich. This, probably, is why manipulators have been buying the shares of the mine.

The work heretofore reported by us as under way in Ophir and other north end mines, is being vigorously pushed with good results expected to follow soon. In Best and Belcher they should report good

ore before long. Several levels are being opened in Gould and Curry. Now that the refuse and other poor stuff in Savage has been milled, and the stock knocked down under an assessment, it is in order to steadily increase the battery assays. The ore they are milling justifies higher battery assays than \$17, although the latter is an improvement on recent returns. They have a good body of ore, going over \$35 a ton, on the 1300-foot level. In Hale and Norcross a reported rich strike can be looked for at any time after the 10th or 15th of this month. In Chollar, work is under way to develop the ore about the 1200-foot level running toward Potosi. In the latter mine and also in Bullion, work is being done which will cause their shares to have more of a speculative character. It is said that soon after Alpha is assessed, an improvement in that mine, or one near by, will be reported.

Mystery still shrouds the work in Challenge, Confidence and Crown Point, but well-informed miners are very sanguine of a development in one and perhaps in all three of them. The assessments have probably driven in enough stock to justify a strike. Work in the Alta group is being closely watched. In the Bodies, Tuscaroras and Quijotas, the work under way is being closely watched by usually well-informed parties.

The Pacific Cattle bill was not passed by Congress.

Successful Patent Solicitors.

As Dewey & Co. have been in the patent soliciting business on this Coast now for so many years, the firm's name is a well-known one. Another reason for its popularity is that a great proportion of the Pacific Coast patents issued by the

Amalgamation at the Comstock Lode.

(Continued from page 153.)

consumed. As the maximum theoretical production is 306½ pounds of monohydrate for this amount of sulphur, the loss was only 5.1 per cent.

A large part of the chamber acid was concentrated in lead pans to 62° B. and sold. The rest, except small quantities sold to mills, was used without concentration in the bluestone works. The weak tower acid was utilized in making copper-sulphate solution for the mill.

The raw material for the bluestone factory consisted of copper ore, principally carbonates from Walker river, copper matte and precipitate from California, and base hullion. The bluestone made from the hullion was of the highest grade and equal to the best English imported. The product of the factory was sold to amalgamating mills principally; some went to California for the use of the farmers. During several years there was a branch establishment at Carson, which utilized the copper-sulphate solution from the mint refinery.

The Lyon mill used only the refuse from the factory, that is, the scrapings and portions which did not look well enough to be put on the market, or the mother liquor which was too weak for profitable concentration. Usually it employed uncrystallized sulphate of copper made from ore in a special tub. In either case, the copper sulphate held an appreciable amount of iron sulphate, and, at times, an excess of acid designedly introduced.

Sulphate of iron was manufactured in small amounts to satisfy a local demand.

The tailings worked at the mill from 1873 to 1877 inclusive were for the most part of very low grade. They were classified under the local designations of "sulphurets," "slimes" and "sand."

The sulphurets were obtained by purchase from the blanket sluices so extensively used at the Comstock. They were principally iron sulphurets. Those caught near the mills which crushed the ores whence they were derived, oxidized with comparative facility on exposure to the air, and yielded by amalgamation as much as 80 per cent of their contents of precious metal. Those caught at greater distances from the quartz-mills showed no signs of oxidation even after long exposure, and it appeared impossible to extract from them by pan-amalgamation more than 50 per cent of their assay values. The reason for this difference in behavior was not known positively. Sulphurets were obtained only in small amounts, were usually amalgamated by themselves, and made no figure in the production of the mill.

The slimes, during the years mentioned, were all purchased from the stamp-mills whenever these had any to sell. The silver contained in them existed apparently in part as a simple sulphuret (such as argentite), and in much larger measure as a multiple sulphuret (such as stephanite or polybasite). Their chemical composition varied materially. Their chief constituent, clay, was the main cause of the difficulty in treating them.

The slimes were spread out on the ground, all lumps being broken up and allowed to dry thoroughly before being worked. Long experience proved beyond question that this preparatory drying was essential for good amalgamation. In common parlance, the slimes were "oxidized," but the change effected was mechanical rather than chemical.

At Dayton, two pans were reserved for treating this material, which was mixed in the pan with certain amounts of sand. The usual charge was composed of 60 to 65 per cent of slime and 40 to 35 per cent of sand. The sand seemed to act beneficially by cutting up any lumps of slime which might exist, and by clearing the globules of quicksilver from any adhering slimy envelope which, unless removed, would keep the quicksilver from contact with the precious metals, prevent the globules from uniting, and carry them off in the stream of tailings.

The slimes purchased by the mill varied greatly in value, ranging from \$13 to \$30 per ton, with occasional higher values. The slime charges (slime and sand mixed) during the years 1875 to 1877 averaged from \$13 to \$18 per ton.

(To be Continued.)

Complimentary Samples.

Persons receiving this paper marked are requested to examine its contents, terms of subscription, and give it their own patronage, and, as far as practicable, aid in circulating the journal, and making its value more widely known to others, and extending its influence in the cause it faithfully serves. Subscription rate, \$3.00 a year. Extra copies mailed for 10 cents, if ordered soon enough. If already a subscriber, please show the paper to others.

Don't Fail to Write.

Should this paper be received by any subscriber who does not want it, or beyond the time he intends to pay for it, let him not fail to write us direct to stop it. A postal card (costing one cent only) will suffice. We will not knowingly send the paper to any one who does not wish it, but if it is continued through the failure of the subscriber to notify us to discontinue it, or some irresponsible party requested to stop it, we shall positively demand payment for the time it is sent. LOOK CAREFULLY AT THE LABEL ON YOUR PAPER.

BACK FILES OF THE MINING AND SCIENTIFIC PRESS (unbound) can be had for \$3 per volume of six months. Per year (two volumes) \$5. Inserted in Dewey's patent binder, 50 cents additional per volume.

Our Agents.

OUR FAIRNESS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

The red cord runs the entire length. Put up in boxes of 20 feet, or coils of 60 to 80 lbs. For sale by all dealers. W. T. Y. SCHENCK, Sole Manufacturer, 222 and 224 Market Street, San Francisco, Cal.

IMPROVED BELT FRUE ORE CONCENTRATOR.

The Best Ore Concentrator in the market, having double the Capacity and doing its work as close as the plain Belt machine, while its concentrations are clean. It is used in a number of Mills, the most notable of which is the Alaska M. & M. Co's Mill, where 24 Improved Belt Frues are taking the Pulp from 120 Stamps, crushing 350 tons per day, and is giving entire satisfaction as against 48 plain Belt Machines, taking the Pulp from the other 120 Stamps.

Price of Improved Belt Frue Vanner, \$825, f. o. b.
Price of Plain Belt Frue Vanner, \$575, f. o. b.

For Pamphlets, Testimonials and further information apply at office.

ADAMS & CARTER, Agents FRUE VANNING MACHINE CO., Room 15, No. 132 Market Street, San Francisco, Cal.

Protected by Patents December 22, 1874; September 2, 1879; April 27, 1880; March 22, 1881; February 20, 1883; September 18, 1883; July 24, 1888. Patents applied for.

There are Over 2200 Plain Belt Machines now in Use.

THE MONTANA COMPANY (Limited), London, October 8, 1885.
DEAR SIR:—Having tested three of your Frue Vanners in a competitive trial with other similar machines (Triumph), we have satisfied ourselves of the superiority of your Vanners, as is evidenced by the fact of our having ordered 20 more of your machines for immediate delivery. Yours truly, THE MONTANA COMPANY (Limited).

N. B.—Since the above was written the 20 Vanners, having been started, gave such satisfaction that 44 additional Frues and more stamps have been purchased. ADAMS & CARTER.

"TRIUMPH" ORE CONCENTRATOR WITH IMPROVED RIFFLED BELT.

The competitive trials which have been held between the "Triumph" Ore Concentrators, the "Frue" Vanners and other forms of concentrating devices, do not warrant the assertion that the "Frue" Vanner is the best ore concentrator in the market. The fact that the "Frues" have improved (corrugated) belts does not militate against the superiority of the "Triumphs;" for, when desired, they (the "Triumphs") can be mounted with a superior belt known as the "Blasdel" Riffled.

Price "Triumph" Concentrators, with Improved (Patented) Belt - - - \$650 f. o. b.
Price "Triumph" Concentrators, with Plain Belt - - - - - \$550 f. o. b.

We are prepared to guarantee the superiority of the "Triumph" over the "Frue" or any other form of Concentrator, for coin if used be. Circulars and testimonial letters furnished on application.

JOSHUA HENDY MACHINE WORKS,
39 to 51 Fremont Street, San Francisco, Cal.

(PATENTED.)
Both the "Triumph" Concentrator and "Blasdel" (riffled) Belt are protected by incontestable letters patent, granted by the Government of the United States.

Original Empire Mill and Mining Company,
Principal Office, 401 California St., cor. Sansome, S. F.
Location of Works, Grass Valley, Nevada Co., Cal.
GRASS VALLEY, NEVADA CO., CAL., NOV. 10, 1885.
Joshua Hendy Machine Works, 39 to 51 Fremont St., S. F., Cal.

GENTLEMEN—I am pleased to state, in reference to the "Triumph" Ore Concentrators, that four (4) of them were placed in the mill of the Original Empire Mill and Mining Company in April, 1884, and a thorough test made of their practical operation; and their efficiency having been demonstrated, four (4) more were subsequently introduced as the complement of the Twenty (20) Stamp Mill, and the eight (8) have been and are now running with entirely satisfactory results.

At the Ten (10) Stamp Mill of the North Star Mining Company, under my supervision, four (4) are also in successful operation, and from my observation of their practical workings, I am convinced that this form of Concentrators is the equal, if not superior to any other style of Vanners or concentrating devices. (Signed) Supt North Star and Original Empire Mining Co. N. B. When the stamping capacity of the two above named mills was increased, more "Triumph" Concentrators were purchased, and twenty-eight (28) are now in constant successful operation.

NOTICE TO GOLD MINERS!
SILVER-PLATED AMALGAMATED PLATES
For SAVING GOLD!
IN QUARTZ, GRAVEL, OR PLACER MINES. MADE OF BEST SOFT LAKE SUPERIOR COPPER

21 and 23 Fremont St., San Francisco, Cal.

189 Clarence St., Sydney, N. S. W.

"Sensible" Horse Power Hoisting Whims.

The hoisting drum is completely under the control of the person in charge of the hoisting or lowering through the shaft of the mine. As the drum is entirely independent from the driving gears, the operations of hoisting, dumping bucket and lowering can be performed with the horse in constant motion, a feature not possessed by any other horse hoist in the market, and one that greatly increases their capacity by avoiding the loss of time due to stopping and starting the horse. They are very light and compact, and can be packed for transportation by mules. Their cost of erection is very slight, two men, in half a day, being able to put one in place, ready for work. With each Whim, working drawings are furnished, showing in detail the proper construction of Gallows Frame and foundation for Hoisting Whim. We carry in stock the following sizes:

- No. 1.—Capacity with One Horse and Single Line, 800 pounds, 75 Feet per Minute.
- No. 2.—Capacity with One Horse and Single Line, 500 pounds, 125 Feet per Minute.

Weight of machine, 1200 pounds. Total shipping weight, including Sweep, Levers and Sheaves, 1400 pounds.

NATIONAL IRON WORKS

N. W. Corner Main and Howard Sts., San Francisco,

—MANUFACTURERS OF—

Stationary and Compound Engines, Flour, Sugar, Saw and Quartz Mill Machinery.

AMALGAMATING MACHINES. CASTINGS AND FORGINGS Of Every Description

ALL WORK TESTED AND GUARANTEED.

IMPROVED PORTABLE HOISTING ENGINES.

NATIONAL ROCKER QUARTZ MILL.

KENDALL'S PATENT, AUGUST 24, 1886.

CAPACITY, 12 Tons in 24 Hours. 3 H. P.

MARSHUTZ & CANTRELL, Sole Manufacturers.

The Patentee and Manufacturers cordially invite miners to critically examine and pass judgment upon this improved system of milling and amalgamating ores in the following particulars:

1. The cost is less than one-half of stamps of same capacity.
2. The freight to mine is less than one-half of stamps.
3. The cost of erecting is less than one-fourth of stamps.
4. The power to drive it is less than one-half of stamps.
5. The wear is less than one-quarter of stamps.
6. There is no wear except on shoes and dies.
7. In point of amalgamation it is superior to any other machine in use.
8. In its simplicity of construction.

We challenge competition with Stamps, Ball Pulverizers or any other ore crushing machines now before the public.

MARSHUTZ & CANTRELL.

Send for Circular and Price List.

THE GIANT POWDER COMPANY

Manufacture Three Kinds of Powder, which are acknowledged by all the Great Chemists of the World as

The Safest and Strongest High Explosives in the Market.

GIANT POWDER or DYNAMITE,

Of Different Strengths as Required.

NOBEL'S EXPLOSIVE GELATINE," which contains 94 per cent of Nitro-Glycerine, and GELATINE-DYNAMITE, Stronger than Dynamite and even Safe in Handling.

JUDSON POWDER IMPROVED.

FOR RAILROADS AND LAND CLEARING. Is from three to four times stronger than ordinary Blasting Powder, and is used by all the Railroads and Gravel Claims, as it breaks more ground, pulverizes better and saves time and money. It is as dry as the ordinary Blasting Powder and runs as freely.

BANDMANN, NIELSEN & CO.,

CAPS and FUSE for Sale

GENERAL AGENTS, SAN FRANCISCO, CAL.

CALIFORNIA VIGORIT POWDER COMPANY

E. L. G. STEELE & CO., Agents.

OFFICE, 208 CALIFORNIA STREET, SAN FRANCISCO, CAL.

Manufacturers of Nitro-Glycerine ("Dynamite" or "Giant") Blasting Powders.

ALSO VIGORIT "LOW" POWDER FOR EARTH AND WOOD.

Are prepared to supply purchasers in quantities to suit. Contracts made for future delivery and prices quoted on application

IT HAS NO EQUAL.

POSITIVELY FIRE-PROOF.

Can Be Put On by Any One.

Adopted by the Navy.

MAGNESIA SECTIONAL COVERING

For BOILERS, STEAM PIPES, COLD STORAGE, and all places requiring Non-Heat-Conducting Material.

Smelter and Smelting Plant.

We herewith present engravings of the "Pacific" water-jacket smelter for argentiferous lead ore and a complete smelting plant. When it is necessary to reduce the ore at the mine, instead of sending it to another works, a plant of from five to 30 tons daily capacity can be built on the plan shown. One of the "Pacific" water-jacket smelters is shown in full running order, the blast for which is furnished by a Baker blower, driven separately by a small engine. This is for the purpose of securing a steady and uniform blast.

The crusher used is of sufficient capacity to crush in a few hours all the ore and flux required for the entire day. It is also driven by a separate engine, making it entirely independent of the other machinery. The two engines are designed specially for the work. The boiler is of the horizontal tubular type, of ample size to furnish steam for the engines and pumps, and is fitted complete with all accessories.

The Pacific smelter, as now constructed, embodies the results of more than 20 years' experience, observation and study as to the requirements of this method of treating ores. The remarkable results obtained from it regarding capacity, for continuous work, minimum cost of repairs and economic production of bullion, fairly entitle it to be considered as the most improved type of smelter now made.

The water-jacket is made of wrought iron in two or four sections, according to size, so that any of them can be removed without disturbance to the rest of the furnace, making all parts accessible for cleaning out and repairs when necessary. The whole structure is made complete at the shop—constructed mostly of wrought iron, to insure strength and lightness, and in sections, to facilitate transportation and setting up; no brickwork being required except

for crucible and two courses on top of jacket, making the cost of erection less than half that of any other style of smelters.

A holler-iron foundation and curb are provided, inside of which the whole structure is built. This is to prevent any escape of bullion in case of leakage from the crucible, which often occurs, involving serious loss without any means of detecting it.

The lead well is located outside the jacket, into which the metal is run and kept hot by a small fire, while the dross and other impurities can be skimmed off before being ladled into molds. The tuyeres are made in the jacket, and, being surrounded by water in active circulation, never burn out. The jackets are oval in form with round ends, giving no corners for the accumulation of slag, which tend to bridge the ore and prevent it from coming in contact with the blast.

The arrangement of the tuyeres and the distribution of the blast are such as to avoid dead centers, secure perfect combustion and the most economical results from fuel. In the larger sizes both ends are provided with charging doors and slag discharges.

It is a matter of record that these furnaces almost invariably overrun their rated capacity, a result due largely to the perfect distribution and application of the blast. These smelters are made of 10, 20, 30 and 40 tons capacity, the larger sizes being recommended as the most desirable where the ore supply will warrant, as they can be run more economically both as regards fuel and attendance than the smaller. Duplicating the 40-ton stack is recommended when larger capacity is wanted.

In the larger plants separate engines are provided for blower and crusher to insure a steady blast, and for the purpose of being able to vary the speed as occasion may require. Wrought-iron downcasts or fine dust chambers furnished

"PACIFIC" WATER JACKET SMELTER.

COMPLETE SMELTING PLANT FOR ARGENTIFEROUS LEAD ORE.

when desired. The great drawback to the successful treatment of ores by the smelting process, it is well known, has been the want of a smelter that could be run continuously without stopping frequently for repairs. This smelter herewith presented, with the care ordinarily given a steam boiler, can be run as long and with as little loss of time or expense for repair. The Pacific Iron Works of this city have built a large number of these furnaces and complete plants and are prepared to furnish them erected in complete running order in any part of the country.

The Potosi Mining Company has re-elected the following Board of Directors and officers: A. K. P. Harmon, W. E. Sell, Charles T. Bridge, A. W. Rose, Jr. and Joseph Marks. A. K. P. Harmon was re-elected president, W. E. Sell vice-president, Charles E. Elliott secretary, and A. C. Hamilton superintendent.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—Eds.

Inventors and Inventions.

A Coming Celebration of the American Patent System.

EDITORS PRESS:—The completion of the first century of the American patent system marks so important an epoch in the history of the nation that it is eminently proper that the beginning of the second shall not pass unnoticed.

The centennial anniversaries of other important national events have been celebrated in a manner worthy of a people proud of their country and its growth. Surely the system that has aided the agriculturist in the field, the mechanic in the shop, and the toiler in the mine, that has stimulated invention and helped every branch of modern industry, has played no small part in a history so full of the triumphs of human achievement.

Believing that the American inventor and manufacturer of inventions will regard it a privilege as well as a duty to co-operate in making due recognition of these facts, it is proposed to hold a celebration at the National Capital in April, 1891, which shall in a fitting manner commemorate the important event, and place on record the nation's appreciation of the labors of those whose ingenuity, patience and tireless efforts have exercised such a potent influence in accelerating the prosperous growth of the nation, and in aiding the progress of our civilization.

The necessity for a National Association of Inventors organized for mutual benefit has been frequently discussed in the technical and other journals. No time could be more opportune for the formation of such an association than when men from every part of the country meet to celebrate so important an anniversary. Surely the occasion is most inspiring.

This announcement by the secretary, Mr. J. Elfreth Watkins, of the Central Committee, is a clear index of what is to be expected on this occasion.

The Central Committee is composed of Messrs. John W. Babson, Robt. W. Fenwick, B. H. Warner, Prof. Otis T. Mason, M. M. Parker, Hon. John Lynch, M. C. Stone and J. Elfreth Watkins, representing the most prominent business interests in Washington. This committee has the earnest co-operation of Senators Platt and Teller, Representatives Butterworth and other members of the Congressional Patent Committee, and Hon. C. E. Mitchell, Commissioner of Patents, Dr. G. Brown Goode, Curator at the National Museum, Hon. A. R. Spofford, Congressional Librarian, and many other of the officials of the governmental departments.

Commodious rooms for the meetings of the various committees with telephone service have been provided, and clerks are happily engaged ending out communications to inventors, manufacturers and members of Congress with the view of obtaining information as to the most suitable men to be appointed from the different States of the Union as delegates or representatives to the centennial celebration.

The responses are indicative of great interest being manifested by leading inventors of the country, as well as manufacturers of patented articles. Among the many letters of approval received by the committee is one from Mr. Thomas A. Edison, the great electrical inventor, saying: "I am in hearty sympathy with the movement." Prof. Alex. Graham Bell, inventor and patentee of the telephone, has signified his willingness to preside at one of the meetings of the centennial celebration. The President of the United States will preside at the opening exercises; Hon. John W. Noble, Secretary of the Interior; Hon. Frederick Fraley, LL.D., and Prof. S. P. Langley, LL.D., will also preside at different meetings.

The Committee on Literature, consisting of Dr. G. Brown Goode, chairman; Hon. A. R. Spofford, and L. Deane, Esq., have arranged the following order of exercises, which would be very difficult to excel, and which will prove one of the greatest literary treats of the nineteenth century:

First Public Meeting, Afternoon, April 8, 1891.—To be presided over by the President of the United States.

Second Public Meeting, April 8th 7 to 8:30 P. M. To be presided over by Hon. J. B. Noble, Secretary of the Interior.

Special Reception to Inventors and Manufacturers, and the ladies who accompany them, at the Patent Office, April 8th, 9 to 11:30 P. M., by Hon. John W. Noble, Secretary of the Interior, and Hon. C. E. Mitchell, Commissioner of Patents.

Third Public Meeting, Afternoon, April 9.—To be presided over by Hon. Frederick Fraley, LL.D., President of the National Board of Trade and the American Philosophical Society, and Charter Member of Franklin Institute.

Fourth Public Meeting, Evening, April 9.—To be presided over by Prof. S. P. Langley, LL.D., Secretary of the Smithsonian Institution.

Anniversary Day, April 10.—Anniversary of the signing of the first American Patent Law—An Act to promote the progress of the Useful Arts; by George Washington.

To A. M.—Excursion to Mount Vernon, where an address will be delivered by J. M. Toner, M. D., of Washington, upon "Washington as an Inventor and Promoter of Improvements."

Fifth Public Meeting, April 10.—To be presided over by Prof. A. Graham Bell.

Addresses upon the following subjects are promised at the public meetings:

Edward Atkinson, Ph. D., LL.D., of Massachusetts: Invention in its Effects upon Household Economy.

Dr. John S. Billings, Curator U. S. Army Medical Museum: American Inventions and Discoveries in Medical Surgery and Practical Sanitation.

Hon. Samuel Blatchford, Justice of the Supreme Court of the U. S.—A Century of Patent Law.

Cyrus F. Brackett, M. D., LL.D., of New Jersey, Henry Professor of Physics, College of New Jersey, Princeton: The Effect of Invention Upon the Progress of Electrical Science.

Hon. Benj. Butterworth, Ohio, U. S. House of Representatives: The Effect of our Patent System on the Material Development of the United States.

Octave Chanute of Illinois, President of the American Society of Civil Engineers: The Effect of Inventions upon the Railroad and Other Means of Intercommunication.

Prof. F. W. Clarke, S. B., of Ohio, Chief Chemist, Geological Survey: The Relation of Abstract Scientific Research to Practical Invention, with Special Reference to Chemistry and Physics.

Hon. John W. Daniel of Virginia, U. S. Senator: The New South as an Outgrowth of Invention and the American Patent Law.

Maj. C. E. Dutton, Ordnance Dept., U. S. A.: The Influence of Invention upon the Implements and Munitions of Modern Warfare.

Thomas Gray, C. E. B. Sc., F. R. S. E., of Indiana, Professor of Dynamic Engineering, Rose Polytechnic Institution, Terre Haute: The Invention of the Telegraph and Telephone.

Prof. Otis T. Mason, Ph.D., of Virginia, Curator U. S. National Museum: The Birth of Invention.

Hon. C. E. Mitchell of Connecticut, Commissioner of Patents: The Birth and Growth of the American Patent System.

Hon. O. H. Platt of Connecticut, U. S. Senator: Invention and Advancement.

Col. F. A. Seely of Pennsylvania, Principal Examiner, U. S. Patent Office: International Protection of Industrial Property.

Hon. A. R. Spofford, LL.D., Librarian U. S. Congress: The Copyright System of the United States; its Origin and Growth.

Hon. Robert S. Taylor of Indiana: The Epoch-Making Inventions of America.

Robt. H. Thurston, A. M., LL.D., Doc. Eng., of New York, Director and Professor of Mechanical Engineering, Sibley College, Cornell University: The Invention of the Steam Engine.

W. P. Trowbridge, Ph. D., LL.D., of New York, Professor of Engineering School of Mines, Columbia College: The Effect of Technological Schools upon the Progress of Inventions.

Hon. Edwin Willis, of Michigan, Assistant Secretary of Agriculture: The Relation of Invention to Agriculture.

Hon. Carroll D. Wright, M. A., of Washington, Commissioner of Labor: The Relation of Invention to Labor.

Committees on Reception, Public Comfort, Transportation and Finances have been appointed and are actively engaged making reasonable terms with hotels, private boarding-houses and railroad companies, and arranging for a right royal reception to visitors, and in obtaining contributions from the citizens of Washington and the country at large to defray the expenses attending the renting of committee-rooms, public halls and the printing and circulation of information throughout the United States, but more especially are these funds solicited for the publication of two or more handsomely printed volumes of 500 pages each, which shall contain the addresses delivered by the eminent statesmen, political economists and scientists, together with a series of biographies of the greatest American inventors and manufacturers of their inventions. The treasurer of the Finance Committee is Hon. A. T. Britton, President of the American Security and Trust Co.; Chairman of the Reception Committee is W. Oranah McIntyre; Chairman of the Committee on Public Comfort, W. C. Dodge, with sub-committees on Hotels, J. H. Whitaker, Chairman; and on Private Boarding-Houses, E. T. Fenwick, Chairman.

It is hoped that inventors and manufacturers in your section will take a deep interest in the promotion of the celebration of this important event of our country's history.

Washington, D. C. EDWARD T. FENWICK

Washington Mines.

EDITORS PRESS:—After nearly a year's observation and scientific investigation in this State, I am glad to say our mineral resources are immense. Washington is the coming mining region. Not only do I find gold, silver, copper, lead and iron in good paying quantities, but platinum as well. The latter metal is worth at present \$25 per ounce. On a tributary of the Snoqualmie river—ranging river—I find good platinum prospects. It is associated with the placer gold, and occurs in grains and small nuggets. Like the gold, it is more or less water-worn.

We may expect a great variety of metallic products in this State, owing to the diversified geological structure and composition of the mountains. In the Cascade I find, geologically, a fair representation of all the great ranges in the world—igneous or eruptive rocks, metamorphic rocks and sedimentary formations *ad infinitum*.

Through these varied mountain structures, accompanied with various degrees of metamorphism, it is to be expected that a multifarious collection of minerals and metals exist, and so they are found.

The Cascade of Washington, like the Sierras of California, form the depository of practically inexhaustible stores of mineral wealth. For centuries to come man will break treasures from these mountains that, thanks to nature, are replete for his use and progress.

The dense, almost dismal forests of feathery-

topped evergreens lend an enchantment to the student of nature as he traverses o'er the broad fields of unprospected lands.

Almost daily are new discoveries being made that are significant of vast possibilities.

It seems strange, indeed, that so many men rush off to Alaska and the frozen regions north, in search of gold and silver, when just as good a field exists nearer at home. Taking into account the climatic conditions of this State, its mild, temperate winters, surely it will be a veritable El Dorado as developments proceed and more discoveries are made. Already a large number of good ledges have been located and work commenced that will be followed to the deep. To be brief, we are delighted with the Evergreen State and propose to stay with the country.

CHAS. F. BLACKBURN.

Mountain View Wash.

It Is Now Law.

Following is the full text of the law which applies to change of locality of trial in debris suits brought by counties or cities:

SECTION 1. Section three hundred and ninety-four of the code of Civil Procedure of California is hereby amended to read as follows:

SECTION 394. An action against a county, or city and county, unless such action is brought by a county, or city and county, in which case it may be commenced and tried in any county, or city and county, not a part thereto; provided, further, that whenever an action is brought by a county or city against citizens of another county, or a corporation doing business in the latter, the action must be [on the motion of the defendant] transferred for trial to a county other than that in which the plaintiff is situated, if the plaintiff be a city.

Sec. 2. This Act shall take effect and be in force from and after its passage.

As a question of right in common law, there is really nothing in this that is objectionable, because the principle therein contained is correct and has been in practice in all courts. In a case where a court is an interested party, he calls a disinterested judge to preside for him. A man who has a case in court, and has reason to believe that owing to prejudice existing there against him he cannot obtain justice, he applies to the court for a change of venue to some court where he can have an impartial trial, and whenever the court is satisfied on such point he grants the request and it is taken to a court agreed on. Whatever we may think to the contrary, we must have faith in all our courts to do justice, and as each Superior Court has the same jurisdiction, they will no doubt decide cases according to the law, and it does not affect United States Courts.

MARKET PRICE OF SILVER BULLION.—The Acting Secretary of the Treasury, in answer to the Senate resolution, says the basis on which he estimates the market price of silver is the daily quotations of silver in London, New York and San Francisco. The market price the Secretary estimates from a comparison of these prices and the prices at which silver is offered for sale to the Government, the rule being to accept the lowest offers, provided they do not materially exceed the highest market price in the three named cities. Nettleton further states that no silver bullion has been purchased by the Government outside the United States, but undoubtedly large quantities of foreign silver bullion have been delivered on purchases to the Government made from parties residing in the United States.

THE BIG-TREE RESERVATION TO BE CLEARED OF SETTLERS.—Commissioner Groff's report and suggestion on the Kaweah Colony, in which it is proposed to permit the settlers to remain where they are, under specified conditions, on the ground that they would protect the big tree instead of destroying them, does not seem to please Secretary Noble. He will, it is said, prepare a statement claiming that the settlers cannot be tolerated on the reservation, and that if the law cannot reach them, he would recommend that their land be condemned and appraised and the colonists paid for their claims and improvements.

THE APPROPRIATIONS.—The following is an approximate statement of the appropriations made at both sessions of the Fifty-first Congress, prepared by the clerk of the Senate Committee on Appropriations: Amount of regular bills, including the deficiencies and miscellaneous appropriations for the first session, \$361,700,000; amount of regular bills, including deficiencies and miscellaneous appropriations for the second session, \$405,000,000; permanent appropriations for the first session, about \$101,000,000; and permanent appropriations for the second estimated at \$123,000,000. This makes a grand total of \$989,700,000.

THE LAW'S DELAYS TO BE REDUCED.—A recent rule made by the United States Supreme Court will do much to prevent delays that have been vexatious and costly. It provides that all cases must be docketed within 30 days of the taking of the appeal from the decision of the lower court. Before this, litigants whose main motive for appealing a case was to gain time allowed months to go by after notice of appeal before they filed their papers. The rule will be a godsend to the court as well as to honest litigants, for it will reduce the calendar.

Amalgamation at the Comstock Lode.

A Historical Sketch of Milling Operations at Washoe and an Account of the Treatment of Tailings.

NUMBER V.—CONCLUDED.

[By A. D. HOBBS, JR. Read before the American Institute of Mining Engineers.]

The sand was that part of the tailings which had escaped from the stamp-mills, and after passing through numberless blanket sluices and other concentrators, finally had been caught in reservoirs. Some of this material was purchased. By far the larger part came from the company's large reservoir on the flat at the mouth of Gold Canyon, three miles or more from the nearest quartz-mill. Into these reservoirs were led the waters of the creek, carrying not only the residues from the blanket sluices above, but also various impurities discharged into the canyon or washed down by the rains. The inflowing stream was watched night and day by men who decided from its appearance whether it held a sufficient amount of pay material to be allowed to settle in the reservoir, or whether the contents were too poor for profitable treatment, and therefore were to be turned back into the creek-bed. When one reservoir was filled with the water, the stream was led into another, and the material in the first was allowed to settle, the cleared water being then drawn off. In this manner the reservoirs were gradually filled with sand, which was allowed to remain undisturbed for a long time, and then was plowed up and more completely dried under exposure to the air. During the dry hot summers at Dayton, evaporation proceeded at a rapid rate.

The material deposited at the upper end of each reservoir, near the inlet, was left untouched, being too coarse and poor. The remainder, which held a little slime and assayed over \$5 to \$7 per ton, averaging only a shade over \$5 during the years 1875 to 1877, was scraped up and hauled into the mill.

The sand formed 90 to 95 per cent of the whole amount amalgamated in the period mentioned above. It consisted principally of fine quartz sand, whence its local name, and held limited but varying amounts of clay, iron and copper pyrites were distinguishable, but beyond this the mineral composition was doubtful. The quicksilver used for amalgamation by the mills overlooking the original ore had been thoroughly removed by the repeated concentration to which the material had been subjected before reaching the reservoirs.

Although the Janies had discovered and made known the proper method of amalgamating tailings, it was necessary for each mill to work out certain details best suited to its own special conditions. At the Lyon mill tests were being made continually to determine what modifications were required by the varying character of the tailings, and no trouble was spared to make these tests accurate. No experiment was considered satisfactory unless sufficient material had been treated to give results in bullion. Hence, a week's run at least was made in each instance, and often a month was taken to complete a test. Moreover, as an exact knowledge of the results which were being obtained in actual practice was considered a necessary basis for all efforts at improvements, great pains were taken to determine accurately the amounts and values of the material worked.

All the slimes, being purchased, were of course weighed. The sand was measured by carloads. To decide the weight of a load, in the beginning 1200 weighed tons were hauled, and check-tests were made subsequently from time to time.

To determine the value, a scoopful of material was taken from each car and put in a box. At the end of each day the sample thus collected, marked with the date and the number of carloads, was thoroughly mixed and its moisture determined. Sometimes, these samples were assayed each day for gold and silver, but, usually, amounts proportioned to the number of loads were weighed out daily and the assays made once a week.

Four samples were taken daily from the mill—one, of the sand worked in the large pans; another, from the large settlers; a third, of the slime-charges of the small pans; and a fourth, from the small settlers.

In getting the settler-samples, a dipperful was taken from near the surface of the charge just before each plug was pulled, and poured into large huckets. At the end of the day, after thorough settling, the supernatant water was siphoned off carefully, and the residue dried for assay. This method seems preferable to the more usual way of taking the sample from the material as it runs out of the plug-holes. At Dayton, the percentage of yield, calculated from the settler-assays, did not usually differ from that obtained by the bullion-product by more than one-hundredth of the assay-value of the material milled.

Ten one-ounce assays were made of each sample. The silver heads obtained by cupellation were parted in two sets of five heads each, giving a check-assay of the gold, in weighable quantities. As the assay-tables used (Taylor's) were calculated for half-ounce assays, on averaging the results, any error was divided by 20. This gave most accurate results, but entailed a great amount of work. Work, however, was not spared at the Lyon mill.

The pans all ran four hours. With the low-

grade material treated, any increased product arising from longer amalgamation was more than counterbalanced by the increased expense.

While the pans were being charged, live steam was introduced until the pulp was heated to a degree just bearable to the hand. No advantage was derived from greater heat; on the contrary, a higher temperature was apt to volatilize the mercury, which occasionally was found condensed in the caps of the driver. This was taken as proof that the pans had been run too hot.

The salt was introduced at once with the tailings, and the bluestone was added about half an hour later. After the pans had run nearly an hour, and the pulp had been brought into proper condition, the quicksilver was charged.

The amount of sulphate of copper used, while varying with the different materials treated, averaged about 10 pounds per ton for the sand-pans and 20 pounds per ton for the slime-pans, calculated in terms of crystallized bluestone. When the loss of quicksilver commenced to increase, either more bluestone or more acid was charged, according as outside conditions made it more convenient, and always with improved results. The useful effect in such cases, I am inclined to think, was due to the excess of acid, which might act chemically or mechanically on the clay in the mass. It is possible that the acid may have combined with the clay to form alum, which, according to Melagull and Durocher, acts beneficially in amalgamation.

From 2 to 2½ pounds of salt was used to each pound of bluestone. Careful experiments determined decisively that no better results were obtained with greater proportions of salt, and that it was not safe to use less.

The quicksilver charge was 50 pounds to the ton for all tailings (sand or slime) usually coming to the mill. For uncommonly rich slimes the amount was increased.

Much stress was laid on having the pulp in the pan of proper consistency. Repeated tests had shown that better results were obtained with a thick than with a thin pulp. The pulp was considered thick when it would drop slowly (not run) from a stick which had been dipped into the charge. With the right consistency, the mass had a slow, rolling motion, and the quicksilver could be seen in small globules thoroughly disseminated throughout it.

In 1877, a long series of exact experiments was made to determine this question afresh. The results are given below. The column headed "tons per charge" shows the relative thickness of the pulp. Seven tests were made with sand, and six with slimes. One of each (No. 3) misarranged. More than 19,000 tons of sand and nearly 2200 tons of slime-charges were used in the experiments.

In every test a much larger percentage of the silver was extracted with thick pulp than with thin charges. The evidence here seems to be conclusive. With reference to the gold, the results, although not decisive, tend in the same direction. With the richer material (slime-charges) a gain is evident, while with the poorer (sand) the loss per ton of this metal seems to have been reduced to a minimum with both thick and thin pulp.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

AMADOR.—*Cor. Ledger*, March 7: The Keystone mill, after being idle for the past two or three months, started up again last week. We hope this grand old mine will be kept running for some years to come. The sinking of the shaft at the South Spring Hill mine is finished. They will now drive a crosscut drift at the 900-foot level to strike the ledge. It is supposed they will have to drive from 200 to 300 feet.

FOREST HOME.—*Cor. Ledger*, March 7: Stanley Green & Co. propose opening the gravel beds of Forest Home. They contemplate laying a pipe from the Page ranch to Forest Home, a distance of one and one-half miles. There is a crew of men at work already, making pipe and cleaning ditch, all of which has caused quite a stir around here. There are also negotiations on foot for running a bedrock flume from the old Bliss mine through the Devore ranch, which we think will be a profitable enterprise.

BELMONT.—*Ledger*, March 7: At this mine the surface tunnel has been advanced 25 feet during the last week. Twenty-five feet yet remain to be driven before the ore body is reached. The ten-stamp mill is now being put in condition with new shoes and dies.

SUTTER CREEK.—*Cor. Amador Ledger*: The making of the pipe for the Mahoney is being pushed ahead. They have now been working on the job for six weeks, and it will take three weeks more to complete it. A force of men will soon be put to work grading and digging ditch, and this work will take in the neighborhood of a month to finish. D. K. Valentine is up from San Francisco, looking after Mahoney mine affairs. He says that operations will be commenced as soon as the weather is sufficiently settled to enable the men to work.

PLYMOUTH.—The placer miners are out in full force, looking for gold in the gulches where the late rains have washed the earth away and left the shining metal exposed. Some nice specimens have been picked up in the last few days, some pieces weighing as high as one ounce.

El Dorado.

***AROUND GEORGETOWN.**—*Gazette*, March 4: We understand that rich pay has been struck in the Jones Hill quartz mine. Most everybody in the district is either mining or prospecting for a mine. Frank Silva is going for a big lead of decomposed quartz on his town premises which shows big prospects. Wm. Gibbs and Cad Spencer have leased the Bercaw seam mine, east of Hotchkiss Hill, and started to drift. The O. K. quartz mine, just east of town, owned by County Coroner Dr. Spencer, is showing up a large body of good quartz on the tunnel level. We expect to see a mill pounding out bullion on the O. K. next summer. The hoisting works on Van mine are finally completed, and work of extracting and milling ore will now begin. Some new developments have been made on the Bright Hope mine this winter. The main or shaft ledge has been uncovered on the north end nearly level with Dark Canyon, showing a width of ten feet, and free gold throughout. From this point 360 feet in depth can be gained by 560 feet of tunnel along the lode to the shaft.

Nevada.

RICH ROCK.—*Grass Valley Tidings*, March 3: A number of owners of the Federal Loan quartz mine in Nevada district were in town to-day. They were showing specimens of rock from the 300-level of the mine containing sulphurets and free gold. The rock was commented upon very favorably by those who examined it to-day. The owners are confident that they have a rich mine and we hope that their expectations may be realized.

ANOTHER DIVIDEND PAYER.—*Grass Valley Union*, March 11: The W. Y. O. D. Mining Company, which is becoming prominent among the new mining enterprises of the district, declared its first dividend on Monday of five cents per share upon the capital stock of 30,000 shares, amounting to \$500, which will be payable on the 15th inst. The accumulated fund and the reserves of ore now in sight justify the company in commencing the payment of dividends, which it is expected will be declared monthly for an indefinite time. In addition to the payment of dividends, the company is about to put up a larger mill, having purchased the Canada Hill ten-stamp mill, with its complete equipment of four Frue concentrators, pans, etc., which will largely increase the crushing capacity, which is now but a small five-stamp mill. This new improvement, it is estimated, will cost the company \$15,000, but the present product of the mine is sufficient to meet this expense, as well as to maintain the dividends as above stated. The levels opened in the mine now show at least 5000 tons of ore in the stopes, all of good paying quality. The mine is now regularly producing in bullion twice the amount necessary to pay operating expenses. The future of the mine is full of promise.

ST. JOHN MINE.—*Grass Valley Union*, March 4: The west drift from the 150-foot level of the St. John mine is getting into good ore. At a distance of 70 feet west of the shaft the vein is found to be full two feet in width, the quartz being of excellent appearance, containing sulphurets of good quality, and prospects in gold. The quartz indicates that a pay shoot is coming in, and it is the anticipation that the vein will grow stronger and improve in quality as the drift is extended. The vein stands almost perpendicular, with a slight dip to the south. The St. John is considered to be on the same vein as the Coe mine, which is probably the same vein as the Idaho and Eureka, but this has never been practically demonstrated by actual exploitation, although the strength of the vein, and its east and west course, with the general appearance of the quartz, goes to sustain that theory. The St. John mine is located to the north of town, and in the part of the district where but little mining has ever been done, and the opening up of a paying mine in that locality would have an important bearing on the future prosperity of the district.

W. Y. O. D. MINE.—*Grass Valley Union*, March 5: Rich quartz is being taken from the 700 level of the W. Y. O. D. mine. The quartz is liberally sprinkled with coarse gold, and carries high-grade

sulphurets. The vein from which this quartz is taken is two feet in width. The mine is now yielding profitably all the time. The shaft is being sunk for the No. 8 level, and the vein in the shaft is showing a size of four feet between walls.

WASHINGTON.—Work on the Washington quartz mine at Ormonde, which was suspended some weeks ago by the shortness of the water-power, has been resumed again, and the mill is running with its full head of 20 stamps.

ST. GOTHARD.—Good ore is said to have been struck in the St. Gothard mine, near Columbia Hill. This claim is near the famous Delhi, and its principal stockholders are also members of the Champion Mining Co. of Nevada City.

NORTH BANNER DIVIDEND.—*Grass Valley Union*, March 8: The North Banner Consolidated Tunnel Co. declared its first dividend yesterday, the amount being five cents per share, aggregating \$500. This is the commencement of regular dividends, as the company has been accumulating a surplus for some time, with a view to paying dividends regularly when once they were commenced. The company as present organized has been operating for several years, until the mine is well opened, and a good stamp-mill and other structures are erected upon it. The mine itself has paid for all the improvements put upon it in the last 18 months, without any call upon the stockholders. This has been accomplished through the energy and judgment of George Fletcher, the principal stockholder and manager, and John Skewes, superintendent, who may well be congratulated for opening so valuable a mine as the North Banner is now and promises to be for the future. At the meeting of the directors of the company yesterday, T. J. Mitchell was elected secretary to succeed M. J. Farrell, who resigned, as he expects to be absent for some time during the coming season.

ORLEANS.—The Orleans M. Co. contemplate resuming work this season by sinking a new shaft on the property about 200 feet south of the boundary of the Empire claims. The shaft is to be sunk on what is known as the Fillmore location. The company is disposed to sink a vertical shaft, and to a depth of 800 feet. Owing to the flat dip of the veins in the district, the mode of sinking has always been by incline shafts following the dip of the veins. This gives the opportunity to note the characteristics of the vein, and enables quicker and less costly sinking than if the shafts were sunk vertically through the country rock, which is usually harder and more compact than the ground immediately inclosing the veins.

Orange.

ORANGE COUNTY QUICKSILVER.—*Santa Ana Blade*, March 4: A short time since quicksilver was found within sight of Santa Ana and almost within a stone's throw of Tustin, on a portion of the San Joaquin ranch. The discovery of quicksilver at the point above mentioned is largely due to an accident, as has been the case in a great many other valuable discoveries in this State. A little more than a year since a gentleman, who was hunting for building stone on the San Joaquin ranch, was attracted to this butte by the peculiar color of the boulders cropping out, and their large size. While breaking open some of the stones he discovered a peculiar kind of mineral, the character or class of which he could not determine—not being a practical miner or mineralogist. Some of these specimens fell into the hands of Dr. Kimball, a miner and assayer of this city, and the doctor, after a careful inspection, pronounced it quicksilver. Further investigation proved that some of the specimens were very rich in horn quicksilver, or chloride of mercury. Recently one of the owners of the grant has commenced the work of development on the lead, and a couple of men have been at work running a drift into the face of the hill with a view of cutting the veins. So far they have succeeded in cutting through one vein, which is about two feet thick, with a tolerably well-defined hanging and foot wall. The cut will be extended at least 50 feet farther into the hill in the hope of cutting other ledges.

Shasta.

BULLION.—*Shasta Courier*, March 7: Six bricks of bullion from the Iron Mountain mine, estimated to be worth \$700 per brick, were shipped last Tuesday.

IGO.—*Cor. Shasta Courier*, March 7: The contractors on the Crystal tunnel are making good headway. This tunnel is expected to open a good paying vein of mineral, which surface indications point to as being probable. Work on the Chicago is suspended for the present. P. Gibney's mines are not being worked, pending a final decision as to the title of Sec. 16. The Wright boys are doing some successful sluicing in Bogus gulch, with good prospects of finding a rich ledge. Hubbard & Castel have completed a successful run in their astrara of Cold Spring ore. Shirland & Bro. are running their astrara on a new find on their Creighton ledge. E. L. Ballou's astrara is running on his manzanita ore. W. P. Litten's astrara is running on Continental ore. The Eubanks boys are grinding Live Oak ore in their Andrews creek astrara. The rains have started up a good many of the smaller placer prospects about town.

SURPRISE.—*Shasta Co. Democrat*, March 4: The Surprise mine on Salt creek, four miles from Redding, on the old Shasta road, is developing into one of the best pieces of mining property in the county. J. W. Copeland, the owner, is now shipping ore to the Selby reduction works. The rock from this mine averages \$105 per ton in gold.

Sterra.

THISTLE SHAFT.—*Mountain Messenger*, March 7: The report is that gravel that prospects well has been found in the Thistle shaft, near Gibsonville. There was no question about a gravel channel being where the shaft was sunk, for the reason that years ago the lead had been worked in the Chalcedony, Bootjack, Goahead, Brown's claims and others. In the fall of 1889, a contract was taken by two men to sink the shaft to bedrock. The heavy snow of that year came before they had fairly got ready, which, with other causes, contributed to their failure after the shaft had been put down over 400 feet. Near the end of last year F. A. Gourley took the shaft in hand and completed it. The gravel prospects about the same as that found in the adjoining claims on the channel above, and just what will be done is not known, but it is said that a tunnel will be started in Wallace creek to tap the channel at the western end of the company's ground.

GOLD.—Considerable gold has been picked up on the river bank this week. Henry Meyer found a nice specimen weighing about \$15. August Costa panned out a little over \$3 in a short time, besides a few dollars more which was found by different parties.

Siskiyou.

BLUE GRAVEL.—*Yreka Journal*, March 4: Lee, Lash & Co. are still taking out big pay from their blue gravel claim at the Scott Valley wagon-road crossing, about a mile south of Yreka. They have worked through about 60 feet of blue gravel, and still find the bedrock pitching under the hill, with the auriferous blue gravel averaging about five feet in thickness from the red cement covering to the bedrock. The claim has been opened sufficiently for drainage to the pump shaft, some 80 feet deep, so as to permit four drifters to keep steadily at work, who take out about \$25 a day each. As the claim is opened to better working advantage, the drifters can take out considerable more blue gravel. The red cement covering of the blue gravel, which seems as tough as Roman cement, is also taken out and laid one side for slacking by the effects of the sun and air, so that it can be washed, as it also contains gold in good paying quantity. The discovery of a rich paying blue-gravel bed in this claim, of the most extensive character, will no doubt encourage enterprising efforts to find the same channel in various other sections, where traces of it are plainly visible. Louis Gilbert, who has been sinking a shaft in the Kildore hills, about three miles south of Yreka, on east side of stage-road to Gazelle, was obliged to suspend operations some days ago on account of too much water during the late storms, and is now getting ready to timber the shaft and put in a good pump. He feels confident that he will strike blue gravel in another week's work of sinking. It is confidently believed that blue gravel exists under the Kildore hills, as well as at Greenhorn, and that the main channel runs along the east side of Yreka basin, and thence along the old Oregon road, crossing Shasta river at Fick's, extending a little east of north toward Willow creek, Cottonwood creek and Siskiyou mountain. Several locations have lately been made all over this section, with the intention of prospecting for blue gravel. The hydraulic miners at Seiad and vicinity, on Klamath river, are commencing operations this week, the late rains and snow-storms having furnished a good supply of water, sufficient to afford a good average season. With a powerful pressure of water and the use of considerable powder, the great banks will be leveled rapidly in delving to the bedrock for the glittering ore. Good prospects have been found in the Morris & Roberts quartz ledge on Hungry creek, bonded some time ago by Jones & Hazlett, who will undoubtedly make arrangements to open it on an extensive scale during the coming summer. Jilison & Co. are at work getting out blue gravel from their drifts, and will have a very good supply of water for their giants, as there is about five feet of snow on Siskiyou mountain at the head of the ditch and above, to keep the ditch well filled for some months to come.

Trinity.

MILL RUNNING.—*Trinity Journal*, March 7: Just before going to press we learn that the mill on the Chloride mine is running day and night and ore is being taken out to keep the mill going. We expect the Buck's Ranch mill is also running.

Tuolumne.

BADGER.—*Union-Democrat*, March 10: We understand that the Badger mine, situated near and below the Rawhide mine, in the western part of the county and now bonded to Geo. Stayton, is looking well as the work of development proceeds. The mine was opened years ago, and like hundreds of mines of good promise in those early days, was abandoned, because miners then were not satisfied unless they could rapidly make exorbitant profits. This is all changed now. The abandoned mines of early location are now being relocated and developed and many are in operation most profitably.

HYDE.—The sulphurets from the Hyde mine will be treated at the Reduction Works near town, now owned by Messrs. Kustel, Ahlborn & Melwitz. The news from the Kanaka mine, near Groveland, is very favorable. The mill is in steady operation, giving good results. It is a promising property.

NEW ALBANY.—The work of removing the water from the New Albany mine, the property of Dr. John Walker, will soon begin and mining operations be resumed. Those best acquainted with the ground agree that the lower workings are favorable for profitable returns in the mill. The shaft in this mine is 800 feet deep and drifts have been run at different levels. It will take about six weeks, after work starts, to extract the water.

NEVADA

Washoe District.

CON. CAL. & VA.—*Virginia Chronicle*, March 7: There has been extracted from all parts of the mine during the week 1507 tons of ore, which was shipped to the Eureka mill. The average of all the ore worked at that mill during the week (1545 tons) was \$29.60 per ton. Bullion shipped to Carson mint, assay value, \$49,293.36.

OPHIR.—The west crosscut on the 1300 level is passing into material that gives low assays.

UNION CON.—East crosscut No. 2 on the 1465 level continues in a clay and porphyry formation of a favorable character. Repairs to the shaft are progressing favorably.

MEXICAN.—On the 1465 level No. 1 crosscut east is making good headway without change of formation worthy of note.

ANDES.—During the past week north winze from 350 level was sunk 13 feet, passing through quartz that yielded very low assays. North drift on 420 level was extended 15 feet in a formation of quartz, clay and porphyry.

UTAH.—On the 725 level the northwest drift from the shaft has been extended 48 feet, total length, 526 feet, passing through vein porphyry showing some clay.

OCCIDENTAL.—Extracting ore of fair quality from the stopes on the 400 level. South drift from No. 3 upraise, 40 feet below 450 level, is in 28 feet, showing ore of good quality. South drift from bottom of No. 5 winze, 650 level, is in 113 feet; face in quartz and porphyry.

CROWN POINT.—The west crosscut on the 500 level has been advanced 25 feet since last report; total length, 117 feet. The face is composed of soft

porphyry, with small seams of quartz through it, and a little water running from the face. Are still engaged on repairs on the 600 level.

SEG. BELCHER.—The east crosscut from the south lateral drift on the 600 level is still in a formation the predominant material in which is clay.

CHALLENGE AND CONFIDENCE.—The joint Confidence and Challenge raise from the 750 level is up 172 feet. The joint Confidence and Challenge west crosscut from the north drift on the 1100 level is out 218 feet, 18 feet having been made during the week. The top is in porphyry.

SILVER HILL.—The 500 level is being opened out in a promising formation. There is no trouble on account of water.

KENTUCK.—Good-looking quartz, carrying some metal, is encountered in the raise from the 1000 level. Some pay ore continues to be found in the east crosscut from the north drift on this level. The north drift from the west raise is in material giving low assays.

ALPHA & EXCHEQUER.—Have completed retimbering shaft and resumed work in mine to-day.

WARD COMBINATION.—East drift from the 1800 station is out 870 feet; face in clay and porphyry.

CHOLLAR.—Winze 80 feet south of north line, 750 level, is still going down in a mixture of clay, quartz and porphyry; down 92 feet. Extracted and sent to the mill 496 tons of ore. The ore sent to the mill will average \$17.50 per ton.

BELCHER.—The 1400 level east crosscut has passed through what is thought to be the hanging wall, and has entered vein material composed of low-grade quartz and porphyry. It is out a total distance of 93 feet.

POTOSI.—On the 930 level the east crosscut 400 feet south of north line is out 165 feet; face is in porphyry. The winze is down 80 feet below the 1300 level; bottom in clay and porphyry. East crosscut from winze, 1300 level, is out from the foot-wall 16 feet; face in porphyry streaked with quartz.

JUSTICE.—The north drift 822 level is out 382 feet. The face is in hard ground. We have about 70 feet to go to connect with the bottom of the 622 winze.

CON. IMPERIAL.—Work is still being confined to following up and taking out small streaks of ore on the upper levels and overhauling the old stopes of the mine.

SAVAGE.—During the week have hoisted 776 carloads of ore from the 300, 500, 750 and 900 levels and intermediate below the 1300 level. Shipped to the Mexican mill 534½ tons and milled 450 tons of ore the average battery assay of which was \$7 per ton. Bullion on hand and at the mill amounting to \$24,342.

HALE & NORCROSS.—On the 1100 level the east crosscut on our north boundary has been advanced 22 feet, making its total length 180 feet. The face continues to show low-grade ore. From the east crosscut, 900 level, are stopping ore of fair quality. The north drift from the 800 level of the Hale & Norcross is advanced 50 feet in Savage ground. This drift continues to show fair-grade ore.

OVERMAN.—Have extracted 444 tons of ore. Car sample assays average \$12.34 per ton. Shipped to the Brunswick mill 300 tons of ore. Battery assays average \$14.63 per ton. On the 22d shipped three bars of bullion, valued at \$10,482.

BEST & BELCHER.—1200 level: west crosscut No. 1 has been advanced 22 feet; total length, 162 feet. Face in porphyry, clay and quartz.

GOULD & CURRY.—800 level: The usual amount of ore has been extracted from the old stopes and winze No. 1. South drift from bottom of winze, has been extended 12 feet; total, 22 feet; face in quartz of no value.

Highland District.

ANDERSON.—*Pioche Record*, March 4: Boh McLaughlin, who has been working for some time on the Anderson mine at Highland, has struck some good ore. It was first uncovered several weeks ago and opened up well but immediately pinched again. A few days since it opened better than before and still continues, leading the owners to think the main ore body is found at last, as this claim has produced a considerable quantity of ore in the past from narrow seams and all of a high grade. The claim is situated on the hill north of the Highland brewery and east from the Mendham mine.

Oseola District.

IMPORTANT PLACER STRIKE.—*White Pine News*, March 4: From A. J. Millick, who came over from Oseola Sunday, we learn of a new and important strike made in a placer claim located by Boone Tifford about three miles and a quarter south of Oseola and about a quarter of a mile south of the old Mary Ann quartz claim on the west side of the Snake range. After sinking through a hard-cap about a foot thick and then through five feet of lime, cement pay gravel was encountered, which at the time Mr. Millick left was known to be eight feet thick with bedrock yet to be reached. One hundred shovels of dirt were put through a dry washer, which was but the work of a few minutes, and \$16 was the result. If there was any coarse gold it was not saved, as anything of the value of 50 cents will not go through the screen. About 12 claims have been taken up in the immediate vicinity. The gold is worth about \$16 to the ounce. This showing speaks for itself and indicates that there are possibilities for Oseola that have not been dreamed of up to the present.

GOLD QUARTZ.—A. J. Millick, who has been driving the Union Jack tunnel for the purpose of cutting the Butterfield lode, reports that 262 feet from its mouth the ledge was struck and cut through showing it to be 26 feet wide and carrying gold all the way. At the point where the ledge was cut it is about 140 feet to the surface. The claim is owned by John Butterfield of Boston. The Cumberland, another claim of merit, is worked through a shaft 100 feet deep. A drift from the shaft 40 feet from the surface shows free gold all over the face. This claim is also owned by Boston parties. Mr. Millick thinks the outlook for Oseola at present is particularly bright.

Tuscarora District.

NEVADA QUEEN.—*Times-Review*, March 7: North drift, 650 level, has been extended 28 feet. The vein continues low grade, with a slight flow of water.

NAVAJO.—North intermediate drift from No. 5 chute, 350 level, extended 12 feet. The face is beginning to show good ore, vein fair size.

BELLE ISLE.—The rich ore continues in the 350 stopes. The west crosscut, 450 level, has been ex-

tended 14 feet, cutting a vein of medium grade ore about six inches wide. The south drift from the west crosscut, same level, extended 20 feet; the face is in very hard rock.

COMMONWEALTH.—West crosscut on the 4th level extended 39 feet, face showing seam of clay. East crosscut has been advanced 24 feet all of which had to be timbered on account of cutting into the foot-wall of the vein. Have penetrated the vein five feet, all of which gives low assays. A large amount of water is coming from face of crosscut.

NORTH BELLE ISLE.—North drift from Belle Isle, 450 level, extended 13 feet. Some good ore is beginning to come in the face. The 500 stopes are looking fine. Broke nine cars of first-class and 34 cars of concentrating ore. No. 4 upraise, 600 level, continues to pass through seams of ore lying pretty flat. The leasers are generally doing fairly well, and their ore is pretty clean and high grade.

NORTH COMMONWEALTH.—Hoisted 18 cars first-class ore, assay value \$268 per ton, and 43 cars second class, assay \$19 per ton.

Columbus District.

LEACHING HOLMES ORE.—Walker Lake Bulletin, March 4: The management of the Holmes mine is considering the feasibility of erecting extensive leaching works for the reduction of the vast reserves of low-grade ore which have been passed by in former years as being of too little value to pay for milling. The company has been experimenting on a small scale with the leaching process, and the results of the experiments are more than satisfactory. About 1100 ounces of sulphides were shipped to the Selby smelting works from the Holmes mine last month and netted \$775 above all expenses. The sulphides came from 75 tons of refuse ore from the Holmes waste dumps, treated by the leaching process as an experiment. The success attending the first trial has encouraged the Holmes people so much that works having the capacity for treating 100 tons of ore per day are to be erected in the near future if the price of silver does not drop below that of rock salt. In connection with the proposed new works, Mr. Asa B. Eastwood of the Holmes Co. was in Hawthorne last Sunday inspecting the large roasters and other machinery from the Mt. Cory mill, which is now awaiting shipment to Virginia City. Mr. Eastwood also examined the lumber and timber on hand at Forbes & Tobey's yard and made an inspection of the old leaching tanks of the Cory Co., with the view of purchasing the same if his company decides to build the works. Mr. Eastwood says that the company can work \$10 ore at a profit by the leaching process. At present they cannot touch anything less than \$15 ore, and it requires close figuring to make that pay. He estimates that there are fully 400,000 tons of refuse ore on the dumps, as well as immense quantities of low-grade ore in the mine that can be worked at a profit. And then the mining of the low-grade ore will develop large areas of new ground and it is not improbable that rich bodies will be encountered, as it has proven itself to be most fertile ground in the past.

Pioche District.

THE FURNACE.—Pioche Record, March 4: After a week's effort to get men, a sufficient crew was obtained, and yesterday at noon the furnace blew in again and is now running nicely. La grippe was the cause of the two weeks' shutdown.

White Pine District.

HAMILTON.—White Pine News, March 4: It seems to be an undeniable fact that Hamilton is to be the mining camp of the near future. The ore, which carries 60 per cent lead, some iron and about \$20 in silver, is found in ledges of considerable width. The iron in the ore comes very near meeting all expenses. All is life over that way just now, and old White Pine Mountain is being worked from Sherman town to its extreme north end. Hamilton is the acknowledged center and exhibits considerable life.

ARIZONA.

SLATE CREEK.—Cor. Prescott Courier, March 3: The Slate creek group of mines are on the head branches of the creek, about one mile southwest of the Senator mine, and the same distance east of the Dosoris and Blue Dick mines. There are 18 claims in an area of a mile square, named the Azurite, New Era, Davis Nos. 1, 2 and 3, North Pearl, Helvetia, Albert Hatz, Poverty, West Dunkirk, Dunkirk, San Juan, High Divide, Ridge, Wren, North Wren, South Wren and Esmeralda. Twenty-two persons are owners in these claims. Last fall, in order to get the property in such shape that it could be worked or sold, I made an agreement with the owners whereby I have the authority to dispose of 13 of the claims until next October at a stipulated price per foot. In pursuance of that agreement, I attended to the performance of the title work last year, and am bound to do the same for this year. From eight of these claims, in five years past, about 700 tons of ore have been shipped, averaging in value about \$80 per ton in gold, silver and copper. The ores are heavy in copper and iron sulphurets. From Prescott a wagon-road runs direct across the Hassayampa by Pace's ranch to the foot of the mountain, a distance of 10 miles, whence a pack-trail leads over the range a mile and a half to the mines. It is over this road our ores and those of the Blue Dick and Dosoris mines are taken to the sampling works at Prescott. Following the wagon-road through Maple Gulch past the Senator mine, to the divide between Slate creek and Crook canyon, 14 miles, a trail of a mile in length leads to the mines. The veins are large and well located for working by tunnels. On the property there are nine tunnels, run in on the veins, varying in length from 25 to 250 feet, and a dozen shafts and open cuts, from 15 to 50 feet deep. There are several permanent springs on the claims, and the mines are all wet, so there is plenty of water on the spot for treating the ores, with plenty of pine, juniper and oakwood on the claims and adjacent thereto, and it is safe to say that there is no other group of mines within the same distance of Prescott showing the same amount of ore for the work done, or offering the same inducements for investment.

BRITISH COLUMBIA.

FROM HOT SPRINGS.—Nelson Miner, March 4: Superintendent Thompson reports the United mine looking as if it were sure to be one of the big bonanzas of the Kootenay Lake country. The two-compartment working shaft is down 75 feet, and in ore from grass-roots to bottom. At 50 feet a drift was run on the vein for a distance of 50 feet both ways from the shaft. This work proved the ore body continuous and large, fully 200 tons of ore being extracted in running the 100 feet. At the bottom of the shaft the vein is three feet wide and in solid ore. As work progresses, the indications are that the next 25 feet will expose a larger ore body than either that on the surface or at the 50-foot level. Development work continues on the No. 1, a mine owned by the same company that owns the United. During the winter a drift has been run on the vein for a distance of 100 feet. About 75 tons of high-grade ore was extracted, the character of the ore changing for the better as the drift is advanced. The ore is a carbonate, assaying from \$80 to \$600 to the ton in silver. The vein is about 18 inches wide. Superintendent McGovern reports the shaft on the Skyline down 150 feet. If the ledge is not tapped at 200 feet a crosscut will be run. Work was suspended on the Union shaft at a depth of 90 feet, on account of water. The ore runs from \$80 to \$300 in silver.

SMELETER PROSPECTS.—Nelson Miner, March 4: A well-known railway man, and one, too, that is doing much to attract capital toward the lake country, writes the Miner as follows: "Two companies, or rather two parties with English capital, profess to be able to build a smelter at Nelson, and are negotiating with the Provincial Government for site, etc., but a good live Yankee concern would put them all to flight in the matter of expediency and expedition." The Miner agrees with the railway man; at the same time a little English capital is a handy thing to have lying around loose.

HIGH ASSAYS.—The tunnel in the Silver King is now within 14 feet of the incline shaft, and the noise of the work can plainly be heard in the crosscut at the bottom of the latter. The crosscut is free from water, and there remains only about four feet in the shaft. When connection is made, sinking in the shaft will be resumed, and the tunnel will also be continued on toward the Kootenay Bonanza ground. The same favorable conditions exist in the tunnel—solid ore, carrying away up in silver. The lowest assay obtained this week was \$103 and the highest \$2400. The latter assay was obtained from ore that did not appear to be rich, and the result was quite a surprise to the boys.

PROGRESS ON THE GOLD BELT.—The tunnel on the Wildcat is in 170 feet. Work is now confined to crosscutting the ledge at a point about 70 feet from the tunnel face and to sinking a shaft at a point about 50 feet from the tunnel entrance. John Lodge's Pioneer has a two-foot vein of ore that shows free gold, and next week he will put on an addition to his working force. It is now known that the ore of the Poorman, Royal Canadian, Wildcat and other Eagle Creek gold properties will give a return of over an ounce a ton in gold in actual milling operations.

A NEW DISTRICT.—A report is current in Spokane Falls that a party of prospectors from the Cœur d'Alene country have made rich discoveries on Salmon river, about 15 miles from old Fort Shepherd, and directly on the line of the projected Nelson & Fort Shepherd railway. The ore is said to be gray copper, carrying high in silver. From the description of the location given, the new find is not more than 15 miles distant from the Hall Creek placers and less than 30 miles south of Nelson.

COLORADO.

DUMONT NOTES.—Idaho Springs Gazette, Feb. 28: Work around Dumont has slackened up during the past month, though most of the mines will start up again between this and the middle of April. The last contract on the Elm City has been completed, making the tunnel 330 feet long, with a fine streak in the bottom of the breast. The bids are all in for another 100-foot contract. At the Alexander they have one shift working in one of the stopes. As soon as the mill is ready to run, the force will be increased and considerable development will be done. The management has nearly completed a re-stamp mill at the mouth of the lower tunnel. Ed Bowden & Co. have made a very rich strike on the Big Dipper lode, near the Syndicate. They have over a foot of ore that mills up in the hundreds.

LAWSON.—Markett, White & Co. have made a strike on their lease in the Tabor. Several inches of very rich ore. Another strike of importance is the one made in the lower level of the Orient, which will soon bring this mine to the front. Crosby & Co. have put up a whim on their property on Red Elephant, and are working several men. Another good prospect is the Last Chance, located on Silver creek close to the Jo Reynolds, which has produced some high-grade ore. Ed Fountain has a contract of sinking another 50 feet on this property, which will make the shaft nearly 150 feet deep. This promising property is owned by Mrs. Wm. Raines and others. The Franklin County has now reached a depth of 167 feet, and levels have been started east and west from the bottom with flattering results. Joe Harrison is raising from the second to the first level on this mine, and has six inches of ore. This property has been a steady producer right along. It is owned by Boh Lyons & Co.

IDAHO.

DELAMAR.—Cor. Idaho Statesman, March 4: The main topic of conversation in the camp is the deal lately consummated in the DeLamar mining property, particulars of which have already appeared. A mill will be erected in the spring of the capacity of 100 stamps, and the mine put in shape for a vast increase in the extraction of ore necessitated by the increased number of stamps. A certain number of shares was thrown upon the market here and other parties were given the chance of subscribing for stock, and a grand rush was made by the boys working at the mine and other residents of the camp for shares, and in 24 hours between five and six thousand were subscribed for in DeLamar alone, most of which were taken by the miners, and the number of shares taken was only limited by the number of dollars contained in the purses of the subscribers.

AT SILVER CITY.—Cor. Idaho Statesman, March 2: The Stoddard mine, the pioneer claim of the camp, lies east of the DeLamar group and joins it. It is owned by Regan & Hays, and is now being worked by Senator Jones of Nevada, under the management of John Ludwig of Gold Hill, Nevada. Several other claims belong to this property, but the

work being done is confined to the Stoddard. On the north and west there are several properties that are very promising indeed. The Howe-Manhattan, owned by Davies, Workhill and Howe, is one of the most promising prospects in the camp. This mine has been opened up to a considerable extent, there being about 1500 feet of tunnels and laterals, exposing in many places large veins, some of which are rich in silver. The owners are at present sinking a shaft on the extreme south end of their ground, to cut a vein known to exist there. The Lepley group, also northwest of the DeLamar group, embraces seven claims, all showing good milling ore. Frank Lepley and others are the owners, and they are driving a fine tunnel directly across the property which they intend to make the main working tunnel. Several veins have already been cut, some of which are rich in both gold and silver. Almost immediately north of the DeLamar mines, and adjoining them, is the Alta, owned by T. W. Jones and Steve Ready. This property shows a vein 20 feet wide which looks and prospects well. A shaft has been sunk 60 feet and the owners are building a whim-house and making preparations to sink much deeper.

PINE GROVE.—Idaho Avalanche, March 3: We have been informed by a gentleman who is familiar with the Pine Grove mines, in Elmore county, and the history of the St. Louis Pine Grove mining company, that the company has recently been reorganized and is now in charge of a number of practical St. Louis business men, who propose to work this very valuable holding on its merits—in other words, to do some mining instead of stock speculating. They have had some new surveys of their claims made and are now convinced that their last superintendent was not on the lode which showed so well on the surface, but had been running on a small parallel vein a short distance away. They have engaged Elmer C. Towne, a practical miner and a thorough mining engineer, as superintendent.

WOOD RIVER MINES.—Ketchum Keystone, March 2: The consensus of the opinions of competent mining men seems to be that the ores of the Wood River country are in veins and not in pockets or bunches; that many of these veins are true fissures and therefore lasting, and that there is a fair probability that this will yet prove as much a gold as a silver camp. The recent discovery of the existence of gold in greater or less quantities in all of the iron pyrites in this particular locality, and the other fact that the galenas decrease as depth is attained, while the iron increases, go far to confirm the theory of a gold camp. The fact that the presence of that gold here was not suspected until quite recently proves that the place has been but superficially and carelessly prospected. A result of this knowledge should be to encourage the outlay of both effort and money in the direction of deeper and more thorough and intelligent prospecting, and we think it will. The Wood River region contains a larger amount of low-grade ores than any other we know anything about except San Bernardino county, Cal., but mixed with this low-grade ore there is twice the quantity of high-grade ore that has ever been found in the San Bernardino region.

LOWER CALIFORNIA.

ALAMO.—Lower Californian, March 6: The great rain reached Alamo and temporarily flooded things. Lots of work in the placer mines will have to be done over again. Work on the mines has steadily continued. The Ulises is now 140 feet down and sinking daily. The rock is very rich in sulphurets and enough is produced to keep the Princess mill running. The Ludio continues to develop finely. The Gold Tree has a temporary hoist and producing good rock at 45 feet. A new vein was found Sunday by Santiago Robles near the Ulises, which is very rich. It is supposed to be a continuation of the El Paso. The latter resumed Tuesday under Foreman Church. The Aurora mine and mill are working night and day.

MONTANA.

THE PARROT.—Inter-Mountain, March 2: As soon as the frost is out of the ground, active work will be commenced excavating for the foundation which will be laid of heavy masonry. The engine will be 2x260, two inches larger than any other engine in the camp. The building, an already large structure, will be entirely removed and one to conform to the machinery will be erected. When in position it will be equal to if not larger than the large structure now in course of completion over the Lewisville shaft of the Boston & Montana Co. in Meaderville. Cables will be added and double deck cages, with the exception of the sinking apartment, where it is impossible to use but the single-decker. As soon as these four months after commencement, sinking will be prosecuted to the 1000-foot level. Drifts, levels and crosscuts will be run at every 100 feet and the mine when opened up will be the peer of any in the camp. This mine contains some as fine bodies as can be found in the district.

THE BLUE BIRD.—The closing down of the Blue Bird during the past week was a somewhat serious blow to the towns of Burlington and Rocker, both of them being in a large measure dependent upon that mine. The pumps were raised to the 300 and nothing will be done beyond keeping the machinery in order and preparing the ground in this mine so soft that the water will of necessity do some injury if allowed to stand. So far as can be learned it is the present purpose of the company to do no more work until their present litigation with the owners of the Little Darling is closed. On the other hand, it is understood that the mill will be kept in operation, and in order to keep it supplied the Poorman will be opened up.

THE CAMP.—At the other great mines of the camp there is no news of consequence to chronicle other than they are all working about as they were during the past week. The smelters continue to make their regular shipments, and each and every one of them is kept full to overflowing with ore. The greatest need of this camp at the present time is greater reduction capacity, for as things are at present there is hardly a prospect that does not represent there is a loss of consequence to chronicle their luck, thus making the production greater than the consumption. Mines have been started during the past week that have been for some time inoperative. Chief among this number are the Neptune and Stephens, the former the property of

W. A. Clark, while the latter is the property of the estate of A. J. Davis.

THE CHAMPION.—New Northwest, March 6: The rumors that have been rife for several days of the improved condition of the Champion mine are not without foundation, though some of the stories were greatly exaggerated. Mr. H. H. Zenor states that about Monday the vein in the east level, on which they are drifting, developed a very superior body of quartz, samples of which assay 140 ounces to the ton in silver. The vein covers the hanging-wall, but they have not crosscut it, so that its width is undetermined. In the west level there is a showing of 2½ feet of a fair quality of milling ore, which is being taken out as the work proceeds. The contractors engaged in sinking the shaft have made 90 feet since beginning the work, which now puts the depth at 500 feet, and there is yet 150 feet to be made under the contract.

THE RUBY.—President Halteman, of the American Ruby Consolidated Mining Co., is in the city, and owing to the stringency of the money market has decided that it would be a wise plan to suspend operations on their property temporarily, and accordingly the mine was shut down last Tuesday to await other arrangements of the trustees for proceeding with the work.

THE ZOZEL.—Work was begun last Monday by Contractor C. T. Meador on Zozel property, under the bond recorded a few weeks ago.

THE EMERY.—At the Emery mine the vein of pay rock is still in sight and very uniform in width—from 12 to 18 inches—and always carrying a good body of ore.

UTAH.

CLARA CONSOLIDATED.—Salt Lake Tribune, March 3: Thomas Mackinson is in from Stockton and reports that the Clara Consolidated Co. is making preparations to begin work at an early day on its property. This is the property which Mr. Mackinson has been developing to the extent of his abilities for years, and now that he has incorporated and obtained working capital, the group no doubt will soon become a good shipper. It has some ore in sight and the mine is looking quite well.

THE ELIZABETH.—James McAvoy of Stockton came in yesterday. He has the Elizabeth under lease and is getting ready to soon begin stoping from the good bodies of ore which have been uncovered. He expects to ship much ore in the near future.

BUNKER HILL.—The Bunker Hill mine, lying west and adjoining the Legal Tender, is showing up very nicely. The last ore shipped sold for about \$50 per ton, and there is much of such ore ready for stoping. It runs about 70 per cent lead, hence is a desirable smelter ore.

LITTLE ORE RECEIVED.—The storms of the past few days have so retarded the shipping of ore from the hills that but little is coming in to the smelters now.

MINING MEN ANGRY.—Salt Lake Tribune, March 7: The mining men around town last evening were considerably worked up over the proposal of the Rio Grande Western to raise the eastbound ore rate from Park City. Said several: The Western wants (1) to make Salt Lake and Park City common points. (2) It wants the rate raised from \$7 to \$10, the same as the Salt Lake rate, in order that it may get into that market. You see, the rate being less from the Park than from Salt Lake, the Western cannot haul at less price from Park City than from Salt Lake because of the Interstate law. (3) If the Union Pacific refuse to raise the rate the Western will retaliate by lowering the Bingham-Salt Lake rate to \$7 or even \$6, which will carry all the low-grade ores out of the Territory and ruin the local smelting interests. (4) The Western would rather haul five tons of ore at \$6 or \$7 than one ton of bullion at \$13, and it takes from five to seven tons of low-grade ores to make one ton of bullion. The loss of Park City by the raise in rate would aggregate \$75,000 per annum. The smelters might stand the reduction if there was a proportionate reduction in coke, lime rock, coal and charcoal. But there is no suggestion of this.

WASHINGTON.

THE ADELPHIA SOLD.—Ruby Miner, March 4: The Adelpia, Mountain Queen and Mohawk claims on Ruby Hill have been purchased by the Ruby Hill M. Co. of Spokane, a corporation just organized with a capital stock of \$600,000 for the purpose of conducting mining operations on Ruby Hill. The principal stockholders are O. Jeldness and P. Morrison of Spokane, T. M. Elliott of South Dakota and Andrew Jeldness of Ruby. The vendor of the properties is Andrew Jeldness of this city, who retains an interest in the company. The Adelpia, the first and most prominent of these claims, is the extension of the Fourth of July. There are two leads on the ground, the main one cropping out at both ends of the claim. A 50-foot shaft has been sunk between the two so as to crosscut to each. A 65-foot crosscut to the main ledge shows it to be 13 feet wide, with a clear six feet of ore. The sale of this property was made on sampling this pay streak, which ran \$400 in silver with no lead. Sampling the six feet had given \$600. The ore is precisely the same as the Fourth of July. The claim altogether is more promising than the Fourth was at the same stage. April 1st or sooner, if the weather permits, work will be begun on the Adelpia, with Andrew Jeldness as superintendent. The Mountain Queen is a new claim, having been located less than a year ago. The Mohawk is the south extension of the Wooloomooloo and the lead, while small, carries good ore.

SILVER BLUFF.—Okanogan Outlook, March 3: Gip Chilson came in from the Lime belt after provisions this week and reports very favorably of the Silver Bluff mine, on which he has had a force of men at work for several weeks. In the shaft, at a depth of 100 feet, they have recently struck a body of ore from three to five feet wide, and assaying from 400 to 2000 ounces per ton in silver. They have commenced to sort and sack the ore and will make a shipment of about 10 tons in a few days.

MOHAWK.—Billy Hunt, who recently took a contract to do 100 feet of development work on the Mohawk, was in town last week and reported the mine looking exceedingly well. The ore body is increasing rapidly in width and the quality of the ore is also improving in the most gratifying manner.

MECHANICAL PROGRESS

Detecting Flaws in Metal.

We have already noticed a recently devised instrument for detecting flaws in metal called the "schiesophone." It is an English invention, and the London *Times* makes the following reference to it:

The apparatus consists of a small pneumatic tapper worked by the hand, with which the piece of steel or iron to be tested is tapped all over. Connected with the tapper is a telephone, with a microphone interposed in the circuit. Two operators are required—one to apply the tapper and the other to listen through the telephone to the sounds produced. These operators are in separate apartments, so that the direct sounds of the taps may not disturb the listener, whose province it is to detect flaws. The two, however, are in electrical communication, so that the instant the listener hears a false sound, he can signal to his colleague to mark the metal at the point of the last tap. In practice, the listener sits with the telephone to his ear, and so long as the taps are normal, he does nothing. Directly a false sound—which is very distinct from the normal sound—is heard, he at once signals for the spot to be marked. By this means he is able not only to detect a flaw but to localize it. Under the auspices of the Southeastern Railway Company, a demonstration of the schiesophone was given recently by Capt. De Place at the Charing Cross hotel, in the presence of several members of the Ordnance Committee and other government officials. Some samples of steel, wrought iron and cast iron, which had been specially prepared and privately marked, were tested, and in many cases the flaws therein were correctly localized by the instrument. On the other hand, some bars were broken at points where a flaw was indicated, but where the metal proved perfectly sound. Consequently, however ingenious the invention may be, it can hardly yet be called a practical success.

THE GROWING USE OF WRENCHES.—The number of wrenches sold in the United States, though already large, is constantly increasing, remarks *Hardware*. Large dealers in New York and other cities frequently order 1000 dozen at a time, and a very ordinary order is 100 dozen. Every portion of the country takes them largely, and no particular style seems to sell better than another. A buyer from Germany was in New York last month, and gave an order for a sample wrench of every style and size that could be gathered here. These are to be sent to Germany, and an effort is to be made to introduce, as far as practicable, a full line of American wrenches into that country. Notwithstanding the large demand for these goods, the tendency in prices seems to be downward. Wrenches that were selling two years ago at 35 per cent discount, are now quoted at 50 and 55 per cent. The trade invariably demands an excellent article, and a poor wrench is, as a rule, unsalable. Inventors, within the past few years, have sometimes been so unfortunate as to place themselves in the hands of manufacturers, who, in their endeavors to place a cheap article on the market, have sacrificed quality only to reap what seems to be an inevitable result, failure. Not long ago one manufacturer lost \$30,000 in such an attempt. It was with the greatest difficulty that he could sell the second lot to the same party, and the third order never came. The export trade in wrenches is constantly increasing, the American article meeting with high favor in many countries abroad.

HARDENING STEEL PLATES.—Experiments have recently been made to ascertain whether it can be confidently stated that oil-hardening and annealing, or some such process, is necessary for steel plates. Messrs. Brown and Messrs. Cammell, the two great Sheffield firms, makers of compound armor, are now satisfied as to this necessity. A 9-inch plate of steel was manufactured and out into two plates, each 4 feet square. One piece was left untreated and the other was oil-hardened and annealed. They were fired at by the 6-inch gun with Firth steel projectiles weighing 100 lbs. The striking energy of the blow upon the untreated plate was 2389 foot-tons, and the energy of the blow upon that which had been treated was 2378.5 foot-tons. In the latter case the projectile made an indentation of 10½ inches, so that light was just visible through the center of the bulge at the back of the plate. The projectile rebounded, broken into three pieces. The plate was cracked through, but was whole, and no material was splintered out either at its front or back. In the case of the untreated plate, the shot passed through, and the splintering of the steel around the hole in front of the plate spread over a space of 15 inches across. The splintering around the hole at the back of the plate covered a space of 33 inches across. The plate did not remain whole, but went into six pieces.

STRENGTHENING CAST IRON.—A NEW IDEA IN FOUNDRY PRACTICE.—Some of the English iron-founders have adopted a simple practice in making stronger castings. The method is merely the introduction of thin sheets of wrought iron in the center of the mold before casting. This idea was first applied to the casting of thin plates for the ovens of cooking stoves, and a sheet of thin iron in the center of a quarter-inch oven plate renders it practically

unbreakable by fire. Recently the process has been applied to the casting of large iron pipes, a core of sheet iron imparting additional strength and lessening the liability to fracture. As an evidence of the additional strength that may be imparted by this process, it is stated that a plate of iron, one-fourth of an inch thick, cast with a perforated sheet of 27 wire-gauge wrought-iron in the center, possessed six times the strength of a similar cast plate with no core. The quarter-inch plate thus made had the strength of a plate one inch thick.

NAILS THAT LOOK LIKE SCREWS, BUT ARE MADE TO BE DRIVEN.—The newest thing in nails is a twisted wire nail which is a cross between a screw and an ordinary plain wire nail. This idea is of English origin, and it is supposed to represent as great an improvement upon the plain wire nail as that useful invention is over the old cut nail. As is well known, the common cut nail tears and crushes the fibers of the wood as it is driven, and its tapering shape destroys the greater portion of its holding power when it is partially withdrawn. The plain wire nail, being pointed and smooth, does not crush the wood fibers as the cut nail does, but presses them aside. As the diameter of the nail is the same throughout its length, it fits as tightly and holds as firmly when partially drawn as when driven home. The twisted wire nail not only crushes the fibers of the wood less than the two other forms of nail, but by its screw shape possesses a much greater holding-power than either of the other forms. Quite similar to this screw modification of the wire nail is the recent American idea of making a wood screw that will drive nearly as well as a nail and yet can be withdrawn by means of a screw-driver as readily as any screw.

TESTING STEEL AT LOW TEMPERATURE.—The French Government has caused to be made several tests of gun steel at a low temperature—75 to 100° below zero, F. Part of the bars were hardened and part unhardened. The breaking load was increased by the cooling, three per cent in the instance of the unhardened bars, and six per cent in that of those hardened. But in a shock such as a gun would be subjected to, the unhardened bars, cooled, broke on an average with 5.9 blows, against 14.6 blows under ordinary conditions. With the hardened bars the difference was less, 12.57 blows being required for the cold bars, against 14.4 at the normal temperature. The bars—both hardened and unhardened—had their elastic limit raised 11 per cent by the cold, and their elongation was diminished by 12 to 14 per cent. The bars recovered their original properties upon attaining the ordinary temperature.

A NEW BOILER RIVET.—It often happens in riveting boilers that the rivet bulges in the center, resulting not only in the separation of the plates but sometimes in the splitting of one or both of them. In order to obviate this defect, which very seldom becomes known until the boiler comes into actual use, a rivet has been devised which has a thinned waist to allow for expansion and the nucleus of the hurr already shaped. The burr is thus practically started before it receives a blow, and the fiber of the metal is already inclined toward the position it will be ultimately forced to assume. The result is that the rivet-holes become properly filled with the slightly expanded waist of the rivet; the plates are closely united; the hurr is well formed, and there is no danger of the plates cracking. The riveting is also effected with fewer blows, thus economizing labor.

THE MANNESMANN TUBE ROLLING PROCESS.—It is said, is soon to be introduced into the United States. At the present the process is in operation at Remscheid and Bonn, Germany; Kottmatt, Bohemia and Landore, Wales. It is reported that a company is being organized in Vienna, with a capital of \$3,000,000, for the manufacture in that city of these and other tubes. There is an American process for manufacturing tubes by rolling, in operation at Findlay, Ohio, known as the Kellogg seamless process; but it differs from the Mannesmann process in requiring a hollow ingot and a mandrel; while the latter produces tubes directly from a solid ingot. The Findlay pipes are said to be superior to the lap-welded and also cost less.

LARGE BRASS CASTING.—The Lynn brass foundry has just made for the Thomson electric welding company two copper castings supposed to be the largest ever made. They weigh 1500 pounds and are to be used in the welding machines being erected for the United States government for the navy-yards.

COMPARATIVE COST OF WARSHIPS.—It is said the cost of warships per ton is as follows: England, £30 5s.; France, £46 9s.; Russia, £37 5s. The price per indicated horse-power is: England, £30 4s.; France, £56; and the United States, £67 2s.

The best idea of the value of the Bessemer invention may be formed from the simple fact that when Bessemer began experimenting, steel sold in England at from \$250 to \$300 a gross ton. He soon made a better steel at \$30 a ton.

LOCOMOTIVE PRACTICE shows that steel stays bolted on sooner than bolts made from good brands of iron. The fault, which appears to be incurable, lies in the crystalline structure of steel.

SCIENTIFIC PROGRESS.

Cannon-Ball Photography a Delusion.

The following, from the *Scientific American*, explains itself:

In our number for Jan. 17, we published an engraving of what purported to be a photograph of a shell in flight as fired from an 8-inch mortar, taken on the grounds of the Michigan Military Academy, Orchard Lake, Mich. The photograph was sent to us by J. Sumner Rogers, colonel and superintendent of the academy, who stated it was an instantaneous photograph taken during practice firing under the command of Lieut. Frederick S. Strong, U. S. A.

Thereafter we received the following: "Editor *Scientific American*: I notice in your issue of Jan. 17, 1891, a photo-mechanical print from an original negative of a cannon-ball in motion. If I remember correctly, the experimenters in Hungary, in investigating projectiles in motion, used a shutter speed of 0.000076 of a second, and then found the ball had moved visibly during the exposure. Now I wish to state that at any time of day when a shadow as long as that cast by the figure in the foreground of this picture occurs, and with a lens stopped down enough to give a sharp outline of the distant woods and also of the adjacent officer, and a shutter speed sufficient to get the ball at all, such a fully exposed and graded photograph is an impossibility; in fact, I should say that anything more than the faintest outline of the highest lights could never be developed."

HENRY N. POTTER, "Photographic Instructor Natural Science Camp, Canandaigua Lake, N. Y."

We submitted the above letter to Col. Rogers, who in reply informs us he believed the picture to be genuine, but now finds he foolishly allowed himself to be deceived by a dishonest photographer, who "intensified" the ball so as to make it show in the picture. The colonel regrets, etc.

DO STORMS MOVE IN CYCLES?—The Eureka (Humboldt county) *Times* of Feb. 26, under the head of "Reminiscences of Former Anniversaries"—Feb. 22d—gives an interesting article showing a remarkable regularity in the recurrence of severe storms on or about Feb. 22d, occurring at regular intervals of ten years, from which we extract as follows: Thirty years ago, Feb. 22, 1861, we find by consulting the files of the *Times*, a fierce storm was threatening which three days later culminated in a thunder-storm, which the *Times* says equaled anything experienced in the "most tempestuous climate." Thirty years later—the recent anniversary—the thunder-storm was a little "previous" instead of being "tardy" in celebrating Washington's Birthday. Twenty years ago a fierce storm also prevailed all over the State, and became a regular tornado in some districts, uprooting trees, unroofing houses, etc. It caused much suffering and loss among the stock of this county. Ten years ago the coast was also just recovering from a great storm. An item appears in the *Times* of the 23d, saying that only one bridge remained on the mail route between Aroata and Weaverville.

CORK WORMS.—Investigation in France proves the existence of two or three types of moths in wine-cellar. The grubs feed on the fungoid growth that forms on the wine-vats and moldy corks. The insect bores and forms galleries in the cork nearest to the glass, and through the holes thus formed, air gains access to the wine, spoiling it. In corroboration of the above, it has been remarked that one of the chief difficulties in bottling wines in California has been in obtaining a supply of perfect corks. About 25 per cent of corks, after examination for fitness, are rejected. It is often found that wine after being bottled oozes through the corks. Various methods have been resorted to, to stop the inroads of these grubs. After soaking the corks in hot water and then in brandy, they are dried, and when they are put into the bottles the tops are coated with a layer of paraffine wax previous to sealing them with ordinary wax. Neither the grubs nor the insects feed upon the wine, but simply use the cork as a place to deposit their eggs, and the coating may possibly prevent their entrance.

CURIOSITIES OF IRON.—Add carbon to pure iron and it becomes steel. Add a hydrocarbon to iron, and steel itself becomes so extensively modified that its properties are not recognizable. Thus steel may be as soft as pure iron. Add hydrogen, in varying quantity, and it has the quality of resilience, as in the watch-spring, or the quality of tenacity, as in the knife or razor, or may be given nearly the hardness of a diamond, as in a file. With steel at a low temperature, from 400 to 450° F., edge tools are produced, the color in the yellow shades; from 500 to 525° various sorts of springs are produced, color blue; while by heating iron to whiteness and plunging it into water, which is mainly composed of hydrogen, files are produced or forms even harder.

EARTHQUAKE PHOTOGRAPHY.—Signor Baratta's device is described as follows: The telephone wire is connected with a subterranean microphone. Before the telephone diaphragm (vertical), and connected with its center by a fine aluminum wire, is a short slip of the same metal, fixed below, and having a curved piece at the top, which rests against a small mirror, movable about a horizontal axis. This mirror

reflects the light from a lamp and lens to photographic paper on a rotated drum. The light is momentarily shut off every quarter of an hour by a shutter arrangement, worked electro-magnetically by the clockwork which moves the drum.

CHEMICAL FIRE ALARM.—A new fire alarm now in use in Sweden consists of a small copper cartridge closed by an India-rubber button and filled with a fire composition. The fuse contains a mixture of potassium chlorate and sugar, and on it is placed a paraffine capsule containing a few drops of sulphuric acid. When the temperature of the room rises above the melting point of paraffine, the sulphuric acid is liberated and ignites the chlorate mixture, which in its turn sets fire to the Bengal light. A fusible metal disk placed in contact with the mixture will also be melted and thus make electrical connection with a call bell so as to sound the alarm at a distance.

SNOW WORMS.—A puzzling phenomenon has been noticed frequently in some parts of Valley Bend District, Randolph county, Va., this winter. The crust of the snow has been covered two or three times with worms, resembling the ordinary outworms. Where they come from, unless they fall with the snow, is inexplicable. The snow is two feet deep, and the crust is too strong for them to have come up out of the ground. A square foot of snow can scarcely be found some days without a dozen of these worms on it.

NEW METHOD OF MEASURING EXPANSION AND CONTRACTION OF METALS.—In the physical laboratory of Colby University, Prof. Edward W. Worley, of Adelbert College, Cleveland, and Prof. William A. Rogers of Colby University, have succeeded in measuring, by means of wave lengths of light, the changes in the length of metal caused by radiation of the temperature. A machine constructed by Prof. Rogers for the special purpose was employed, and changes in length were measured in millionths of an inch.

APPLE BLOSSOMS IN WINTER.—Perhaps every one does not know how easily fresh apple blossoms can be had in winter. Get the ends of branches with plump flower buds and place them in water in a warm, sunny window and they will soon bloom. No doubt many other kinds of trees and shrubs will give as good satisfaction as the apple. Here, says *Vick's Magazine* for January, is an interesting field for experiment.

THE LARGEST DIAMOND DRILL BORING in the world has just been completed in Saxony. This hole was drilled near Schladebach for the purpose of testing a coal formation. Three and a half years were consumed in drilling this hole with a diamond drill. The hole is about 11 inches in diameter at the top and 2 inches at the bottom.

SCIENTISTS say that the orange was originally a berry, and its evolution has been going on for more than a thousand years.

BET SUGAR.—The annual meeting of the Western Beet Sugar Co., which is the name of the firm operating at Watsonville, was held on Monday of this week. The old directors and officers were re-elected, and these include Claus Spreckels as president, and W. C. Waters, superintendent, at Watsonville. An evening paper states that the reports of the operations for 1890 show that year to have been a very profitable one. The product of the factory at Watsonville was 2128 tons of sugar, which netted the company \$102 per ton. The profits of the year amounted to \$40,000. Dividends could have been declared, but it was decided to spend the surplus in improvements. The company owns a ranch of 1200 acres at Watsonville, all of which have been sown to beet cultivators. A very large crop of beets is expected for this year. A railroad is being continued from the ranch to Salinas City, which will go through a beet-raising country.

A GOOD USE OF ALLIGATORS.—Louisiana planters are finding that the slaughter of alligators has allowed muskrats, the great enemies of levees, to increase at an alarming rate. South Florida people have discovered that the rapid decrease of alligators in the peninsula has been accompanied by a corresponding increase in the muskrat, the most venomous of American snakes, and the alligator's choicest food. The saurian isn't pretty, but he is a friend of humanity, nevertheless.

THE CABLE RAILWAY INVENTION.—The Mechanics' Institute committee appointed to report on the testimonial to be given A. S. Hallidie, inventor of the cable railway, and the first to operate a cable line, has decided to express its appreciation of the value of the invention by spreading commendatory resolutions on the minutes of the Institute and sending a properly engrossed copy to Mr. Hallidie.

A LARGE flow of natural gas was struck in the southern part of the city of Stockton. The well is down 1700 feet, and boring is continued. The present flow of gas is 35,000 feet per day. The new granite courthouse is being heated with natural gas from the county's well with perfect satisfaction.

USEFUL INFORMATION.

A SILENT PIANO is one of the latest inventions. Its object is to do away with the torture inflicted on those who are compelled to listen to the strains of that instrument as invoked by beginners who are learning to make a better use of that valuable instrument. Efforts in this direction have been attempted by covering the instrument with plush or leather which would at the same time lend itself to ornamental effects and considerably reduce the volume of sound. The latest invention, however, is called a "pianophone," and is designed to meet the wants of students of keyboard instruments, by allowing them to practice scales and exercises without interfering with the convenience of involuntary listeners, while still able themselves to hear the results of their performance. It consists of a simple but effective striking action, and the substitution of metallic plates for the ordinary strings, acoustically tuned to the ordinary scale, and yielding sufficient sound to make the playing on the instrument distinctly audible to the player, and even (as in the case of the "silent violin") a source of pleasure to him, while it is inaudible at any distance—such, for instance, as an adjoining room. One great advantage is that the instrument never gets out of tune, and it is easily moved from one place to another.

A USEFUL INVENTION.—An automatic machine which forms, fills, weighs and seals packages is being introduced into factories where large quantities of fine-cut tobacco, soda, starch, etc., are put up. The operations of the machine are curious and novel in every particular, and yet quite simple. The machine consists of a series of forming blocks, receptacles, folders, gammers and feeders, all working in harmony, so that the packages are being smoothly and continuously produced. The forming blocks successfully size the paper, which instantly afterward is wrapped around them, folded and gummed at the end. The paper sacks are then plunged into receptacles, filled, folded on top and sealed. The manifest saving in labor thus effected would seem to warrant the claim of the inventor that if the machine is worked to its full capacity it will pay for itself in 275 working days.

DAMAGED EGGS.—It is an interesting fact that local commission merchants are selling cold-storage warehousemen because about \$12,000 worth of eggs were stored for them during March, April, May and June last year, but owing to carelessness, the apartments where the eggs were stored became filled with the odor of ammonia and other chemicals, permeating the eggs and destroying their market value. The same end for represent the difference between the price which the eggs in good condition would have brought and the actual sums for which they were sold. The "fresh egg" surely has many ills besetting it, and, according to the allegations of the merchants, their eggs might as well or better have remained under the barn or alongside the strawstack as to have been treated as they were.

SOLDERING METALS TO GLASS OR PORCELAIN. M. Callietet has devised a simple method for connecting glass tubes to metal work in the construction of physical apparatus, says *Industries*. The end of the glass tube is first gently warmed and then covered with a few drops of a solution of neutral platinum chloride and camomile oil. On gently warming the tube to a dull redness, the platinum salt is reduced to the metallic state and a brilliant deposit of the metal is formed on the end of the tube. The tube is then connected to the negative electrode of a battery and immersed in a bath of copper sulphate, when the copper is deposited as a malleable adherent coating on the platinum flux, and thus forms a material which can be brazed on to brass or copper in the ordinary way.

HOW TO CLEAN RUBBER SHOES.—A correspondent of an Eastern journal says there is a homely fact that people ought to know in these days, when we are getting a taste of an old-fashioned winter, so that rubber shoes are in frequent requisition by all classes. He wishes to make it known that the easiest way to clean rubber shoes of any kind is to rub them with vaseline. They then clean much better and last longer than if they are washed with water.

TO CURL FEATHERS.—After the curl has come out of them by washing the feather or getting it damp, place a hot flatiron so that you can hold the feather just above it while curling. Take a bone or alver knife, and draw the fibers of the feather between the thumb and dull edge of the knife, taking not more than three fibers at a time, beginning at the point of the feather and curling one-half the other way. The hot iron makes the curl more durable.

PRESSED PAPER PULP has been suggested for railway ties. The various uses to which this material has been put since the introduction of the wood-pulp process gives rise to the suggestion. There seems to be no good reason why it could not be put to this use.

HENS worth \$2000 apiece attracted curious sightseers at a recent poultry show in New York.

ENGINEERING NOTES.

WATER-POWER OF LAKE SUPERIOR.—Col. Hope of London, says the *Canadian Manufacturer*, has organized a company for utilizing the enormous water-power of Lake Superior and constructing very extensive works in the vicinity of Sault Ste. Marie. The waters of Lake Superior fall at the Sault about 30 feet to the level of Lake Huron, and the velocity has been recorded by Gen. Powell of the United States service as a little more than 90,000 cubic feet a second. Col. Hope, who has just returned from spending several weeks on the spot, made careful and accurate measurements and calculations, and finds the actual velocity and volume of water to be equivalent to 236,000 horse-power. His company intend to build a tail-race five miles long on the Canadian side and a canal five miles long on the American side. These canals will be each 1000 feet wide, the widest in the world. They will construct large drydocks on both sides, to be filled and emptied by gravitation. They will be the only drydocks in the world filled and emptied by this method. On the Canadian side all the principal works will be above the rapids, and on the American side below the rapids. The reason of this is that the land for factories and mills is furnished on the Canadian side above and on the American side below the rapids. There will be blast furnaces and shipyards, and it is expected that there will be paper-mills, pulp-mills, flour-mills and other industries, whose motive-power will be supplied by this company or by one of the several subsidiary companies which it is the intention of Col. Hope's company to form.

TO CONNECT THE LAKES WITH THE OHIO.—There seems to be no end to the proposition of new and important engineering enterprises, and the wonder is that their possibility and commercial value have not before been brought to public notice. The large concentration of capital and the necessity of seeking new avenues for its profitable investment no doubt have much to do with these activities. One of the latest propositions in this connection is that connecting the waters of Lake Erie with the Ohio river. The commission appointed to consider the feasibility of this plan reports that it is entirely feasible and comparatively cheap, the water supply being found ample and the grades offering no serious impediment to the work. With the Lake Erie and the Ohio river ship canal constructed and the canal from Buffalo to Albany enlarged to the same dimensions, a chain of inter-waterway communication would be established between New York and New Orleans. Its importance would not be greater commercially than from a military point of view in giving control, for defensive purposes, of the lake front, and in furnishing safe communication between New York and New Orleans and all interior points.

A GIANTIC ENGINEERING SCHEME.—It is seriously proposed to connect three cities—New York, Jersey City and Brooklyn—by tunnels. Articles of a corporation to do the work have already been filed. Four tunnels, large enough for two ordinary and two express trains, are to be constructed, by which not only the three cities named will be connected, but the different surface railway systems of the cities will also be connected. Enormous elevators will lead to commodious passenger and freight depots under ground, thus solving for all time the question of continuous and steady transportation at all hours for freight and passengers in the metropolis. The directors of the new company are all well known in commercial and financial circles. The capital stock is \$5,000,000. The tunnels will be made wide enough for the tracks to be built in the very best manner and delivered ready for use for not to exceed \$1,250,000 per mile. This does not cover, however, the cost of anything but the tunnel itself. The cost of excavation for underground stations, switches, real estate for surface stations, plants for ventilation and lighting, and equipment will have to be added to this cost.

LOCOMOTIVE TOWAGE FOR CANALS.—In Germany, experiments have recently been made with small locomotives for towing heavy boats on canals. Instead, however, of attaching the rope to the locomotive, it is attached to a heavy towing-car, which is drawn by the locomotive. The plan is said to be satisfactory.

A GREAT ENTERPRISE.—The construction of the great reservoir which is to supply Bombay with water is one of the most important engineering works of modern times. The dam will be two miles long, 118 feet high and 103 feet wide at the base. On the top of this big dam is to be a roadway 24 feet wide.

THE CUNARD LINE has contracted for two fast ocean racers of 12,000 tons each, capable of making the trip from Liverpool to New York in five days and eight hours. They will cost \$2,000,000 each, and be ready in 1892.

A SUBMARINE TUNNEL from Long Island to Staten Island has been authorized by Congress. The bill was signed by the President on Feb. 14th. Erasmus Wyman is at the head of the enterprise.

GOOD HEALTH.

INFLUENCE OF THE WIDTH OF STREETS ON PHTHISIS.—According to an American contemporary, remarks the *London Lancet*, Dr. Anders has been making certain inquiries in Philadelphia as to the influence of the width of streets on the mortality from phthisis, the wastage away of bodily tissue, and as the result of examining into the localization of 1590 deaths, he has arrived at the conclusion that the number of phthisis deaths is smaller in proportion to the population in wide streets than in narrow ones, and that in narrow streets the mortality is greatest where they are long, or where they form cul-de-sacs; in other words, complete movement of air about dwellings is a point of great importance in connection with the question of pulmonary phthisis. It is on this principle that all modern by-laws as to open space about houses are based, and it is as important to have wide, open spaces behind houses as well as in the streets in front, so as to secure a proper thorough current of air. There is, as a rule, not much difficulty in getting a reasonable width of street in the case of newly laid out areas for building, but there is a constant tendency to put an undue limit on the needed area behind dwelling-houses, although this is a matter of the first importance as regards the promotion of health and the prevention of a certain class of diseases. The observations from Philadelphia deserve the consideration of such sanitary authorities in this country as have not yet acquired proper control over the open spaces to be provided about new domestic buildings.

A WARNING TO DOG OWNERS.—Professors of canine pets will do well to take warning, says the *London Lancet*, from certain recently reported observations of Prof. Nothnagel. These go to prove that the development of cysticercosis in the human subject is in some cases to be attributed to contact with the saliva of lap-dogs which have been allowed to lick the faces and mouths of their owners. The explanation is a feasible one, and adds a noteworthy contribution to our knowledge of morbid etiology. The *taenia echinococcus*, as is well known, inhabits the small intestine of the dog, and it is highly probable that the ova occasionally find their way into the animal's mouth; for example, in vomiting. There are various æsthetic reasons why the kiss of even the most cleanly and most friendly pug or terrier should be dispensed with. We have now, thanks to the Viennese observer, a still stronger argument to urge against this practice. It may, indeed, like the others, fail to daunt the too-devoted master or mistress, but we cannot do less than avail ourselves of this opportunity to forestall, if possible, by a timely warning, the sharper teaching of experience.

HOW VARIOUS NATIONS SLEEP.—In the tropics men sleep in hammocks or upon mats of grass. The East Indian unrolls his light portable charpoy or mattress, which in the morning is again rolled together and carried away by him. The Japanese lie upon matting with a stiff, uncomfortable wooden neck-rest. The Chinese use low bedsteads, often elaborately carved, and supporting only mats or coverlets. A peculiarity of the German bed is its shortness; besides that, it frequently consists in part of a large down pillow or upper mattress, which spreads over the person and usually answers the purpose of all the other ordinary bed-clothing combined. In England the old-fashioned bedstead is still the pride of the nation, but the iron or brass bedstead is fast becoming universal. The English beds are the largest beds in the world. The ancient Greeks and Romans had their beds supported on frames, but not flat like ours. The Egyptians had a couch of a peculiar shape, more like an old-fashioned easy-chair with hollow back and seat.

CURING COLDS.—A contemporary gives the following suggestions for curing colds: 1. Bathe the feet in hot water and drink a pint of hot lemonade. Then sponge with salt water and remain in a warm room. 2. Bathe the face in very hot water every five minutes for an hour. 3. Snuff up the nostrils hot salt water every three hours. 4. Inhale ammonia or menthol. 5. Take four hours' active exercise in the open air. A ten-grain dose of quinine will usually break a cold in the beginning. Anything that will set the blood actively in circulation will do it, whether it be drugs or the use of a brook-saw. The following has been tried with very beneficial results for cold in the head: One teaspoonful of mustard dissolved in a tumblerful of cold water, and used as a gargle three times a day, will often effect a speedy cure. In more obstinate cases, equal parts of castor oil and pulverized alum, used as snuff, it is stated, will give instant relief.

The use of glycerine on a dry skin does not agree with it.

RAMIE.—The California Ramie Co. has incorporated. Directors—William and R. Lichtenberg, William H. Murray, H. Francis, Arnold Becker, J. W. Lucas and Joseph F. Forrester. Capital stock, \$100,000, of which \$75,000 has been subscribed. Its object will be the cultivation of the ramie plant, reeling its fiber and preparing the same for market.

ELECTRICITY.

The Marvel of the World.

The electric spark has kindled a fire of enterprise which burns with a most steady and increasing force. It was a mystery at its start and it continues a mystery to-day. It was first discovered by our Franklin, as it sprang from its lair in the clouds. The studies and suggestions of that great philosopher soon taught men how to cause it to curb its violent course and to run peacefully along an artificial highway to its quiet home in the earth.

The possibility of capturing and taming this hitherto violent agent soon suggested itself to inquiring minds, and we next find it disciplined, directed and controlled, and made perfectly subservient to the will of men—a peaceful and quiet laborer in the fields of industry. Until 10 or 15 years ago the only use made of it was in feeble currents running along a slender wire simply carrying the thoughts of its captors by telegraph or telephone.

Since then what a change has taken place! At the bidding of science this wonderful and mysterious agent, so terrible in nature, so tame and obedient to its new-found master, is now as completely under control as is the ponderous steam hammer which will simply crack a nut or weld into shape the heaviest mass of iron which is employed to propel the most powerful ocean steamer! Even in its most terrible manifestation of power it can be localized or at will sent quietly along a tiny rod of metal to exert its tremendous power miles away wherever it is directed. Its light is employed to illumine "my lady's bonnet" with the mildest rays which should fall upon the face of beauty, or burn with the most vivid brightness from our beadlands and capes to warn the storm-tossed mariner of a dangerous coast.

It annihilates both time and space or stands a quiet sentinel at the street corner. Every morning it hings to the "autocrat of the breakfast-table" the news of the world as collected and condensed by hundreds of busy minds in every part of the globe. In its speedy work it spans continents and traverses ocean depths as though they were here of space and continuity. Its home is in the heavens and upon the earth. It comes and goes at our bidding with the mighty force of the elements or like the gentle fanning of a zephyr. Its workshop is the universe. Its entity is as unknown as the secret of the Sphinx. The story of its installment as an industrial force is one of the romances of history, and no legend of olden times or sober statement of modern facts is at all on a par with its wonderful accomplishments or rapid development.

THE ECONOMY OF LARGE DYNAMOS. It is said, will not come in their first coat, but in the expense in running them after installed. A 400-horse power generator will cost to manufacture twice as much as a 200 horse power machine. About twice as much material will be put in the former as in the latter, unlike a steam-engine, but there will be a saving in winding the fields and armatures. The larger casting and a greater difficulty in finishing the base and other casting pieces will make up to an extent that which will be saved in winding the fields and armature. After the machines have been installed and put into operation, comes the saving. Less care and consequently labor will be required to keep them running properly, and as the speed will be materially lower, averaging from 300 to 400 revolutions per minute at their maximum, the possibilities of burning out an armature are much reduced from what they would be with an 80-horse power generator, whose armature makes from 700 to 800 revolutions per minute.

A WOMAN'S DEVICE.—Mrs. Mary Lowell is known as the "Electrical Star," according to the *New York Press*, and lately turned her love for electrical engineering to practical account. She was without a servant, and determined to try whether she could not light the kitchen fire by means of a flash of electricity, and then let it burn up before she got up herself. She prepared wires to and from her head to the kitchen grate, and with the aid of a small battery, all that remained to be done was to so "build" the fire that the materials should become more easily ignitable. In the morning, the current was sent through the wires, and when she descended to the kitchen the kettle was boiling. She thinks she has done something toward the solution of the servant-girl question.

ELECTRICAL BLEACHING does not appear to have been the success which was promised, says the *Textile Recorder*, but inventors are not deterred from patenting modified processes. The last is from St. Petersburg, and is for an electrolytic method for preparing a liquid suitable for bleaching tissues and paper pulp. It consists essentially of passing an electric current into a solution of common salt mixed with caustic lime. It is supposed that there is formation of hydrochlorite of lime and hydrate of soda, by which the bleaching process is effected.

THERE is to be a food and health exposition held in New York in March, its projectors wishing to teach the lesson that if people had proper food far less money would be needed for physicians and hospitals.

SAN FRANCISCO:

Saturday, March 14, 1891.

TABLE OF CONTENTS.

EDITORIALS.—Smelter and Smelting Plant, 161. Passing Events; Mining Bureaus; The Mines of Washington; Water Supply of Cities; Assayers' Manual; Gold Bullion for Export; Cleaning Plates, 168. Amalgamating Gold, 169.

ILLUSTRATIONS.—Pacific Water Jacket Smelter; Complete Smelting Plant for Argentinian Ores, 161. Attwood's Amalgamator; Eureka Rubber, 169.

CORRESPONDENCE.—Inventors and Inventions; Washington Mines; It Is Now Law; Market Price of Silver Bullion; The Big Tree Reservation to be Cleared of Settlers; The Appropriation; The Law's Delays to be Reduced; Amalgamations at the Comstock Lode, 162. A Trophy Won for California, 163.

MECHANICAL PROGRESS.—Detecting Flaws in Metal; The Owing Use of Wrenches; Hardening Steel Plates; Strengthening Cast Iron; Nails That Look Like Screws, but Are Made to Be Driven; Testing Steel at Low Temperature; A New Boiler Rivet; The Mannesmann Tube Rolling Process; Large Brass Castings; Comparative Cost of Workshops; Miscellaneous, 166.

SCIENTIFIC PROGRESS.—Cannon-Ball Photography; A Delusion; Do Storms Move in Cycles? Cork Worms; Curiosities of Iron; Earthquake Photography; Chemical Fire Alarm; Snow Worms; New Method of Measuring Expansion and Contraction of Metals; Apple Blossoms in Winter; Miscellaneous, 166.

USEFUL INFORMATION.—A Silent Piano; A Glass Invention; Damaged Eggs; Soldering Metal to Glass or Porcelain; How to Clean Rubber Shoes; To Cut Feather; Miscellaneous, 167.

ENGINEERING NOTES.—Water-Power of Lake Superior; To Connect the Lakes with the Ohio; A Organic Engineering Scheme; Locomotive Towing for Canals; A Great Enterprise; Miscellaneous, 167.

GOOD HEALTH.—Influence of the Width of Streets on Phthisis; A Warning to Dog Owners; How Various Nations Sleep; Curing Colds; Miscellaneous; Ramble, 167.

ELECTRICITY.—The Marvel of the World; The Economy of Large Dynamoes; A Woman's Device; Electrical Bleaching, 167.

MINING SUMMARY.—From the various counties of California, Nevada, Arizona, Colorado, Idaho, Montana, New Mexico, Oregon, Utah, Wyoming, 164-165.

MINING STOCK MARKET.—Sales at the San Francisco Stock Board, Notices of Meetings, Assessments, Dividends, etc., 172.

MARKET REPORTS.—Local Markets, Eastern Metal Markets, etc., 172.

Business Announcements.

Passing Events.

The question of ore rates on railroads is a very important one to many mining districts. They have had difficulty in this connection in Idaho and Montana, and now Utah is worried over a proposed advance of \$3 per ton from Park City to Denver and the Missouri river. The mining men at Salt Lake are vigorously protesting.

Some of the mining counties of this State are commencing to think of preparing suitable exhibits for the World's Fair. Both Nevada and Placer counties will consider the idea of sending a 1000-pound brick of native gold.

Quite an activity is again apparent in the local mining share market, and some sharp advances have been made in certain Comstock securities this week.

The danger of the closing of the State Mining Bureau by the Legislature is past, and it is probable that the institution will have an appropriation of \$50,000 this year.

Grass Valley has another dividend-paying mine on its list in the W. Y. O. D. claim, which this week announces its first dividend.

Mining Bureaus.

The California State Mining Bureau did not fare so well at the hands of the Legislature this session as it did last, when an appropriation of \$100,000 was made. Last week the Assembly gave it \$40,000 in the General Appropriation bill, but the Finance Committee of the Senate has raised this to \$50,000, which will probably be the amount. While this cannot be said to be a liberal appropriation, it is more than the Bureau has ordinarily had until last session. In fact, the friends of the Bureau can well be satisfied in view of the opposition to State Commissions, for even the abolition of this, among others, was advocated by some members.

A disposition was manifested to cut off field work and confine the efforts of the Bureau to its museum department. The truth of the matter is, however, that the main practical value of such an institution to the mining public is its field work. The museum is well enough in its way and serves a useful purpose as an exhibition of minerals or mineral products, but as far as actual miners are concerned, they care very little about this. What they want a Bureau to do is to bring their districts and mines before the people, inform them as to the methods of beneficiating their ores, and gather and publish such facts as are of daily use in their business.

While the last report may be open to the suspicion of some little "padding," perhaps, and some portions—notably that on mining laws—should have been more carefully edited, on the whole it was creditable, several chapters being of special value. Of course if field work is cut off, the next report must consist mainly of a catalogue of donations to the museum.

But while we have the only Mining Bureau in the mining States, the others are now organizing them. Washington has now a State Geologist, who has just issued his first report. Montana and Utah are both about to start mining bureaus. The bill to establish a State Mining Bureau in Colorado has been favorably reported, and, we are informed, is very sure to pass, so there will soon be a Mining Commissioner there. Under these circumstances, we will soon have mining and metallurgical literature in quantity, so no one need suffer from lack of information on these subjects.

The Mines of Washington.

We have received the first annual report of State Geologist George A. Bethune, of Washington, who has, since his appointment a year ago, inspected every mining district, every mine of promise or prospective worth, and every industrial enterprise horn of the mineral developments of the State. The report is a very useful and interesting one. It gives a history of the placer and quartz discoveries of Washington; chapters on the coal and iron; analyses, descriptions of the metallurgical works, points for prospectors and descriptions of various mines and districts.

It seems from this report that to Washington is due the distinction of being the first division of the Union in which gold was discovered north of California on the Pacific Coast. This was on the Similkameen river in what is now known as Okanogan county, in 1859, when the boundary commission was at work. This just preceded the Fraser river excitement which shortly drew all the men off into British Columbia to that famous region. Discoveries were also made in 1874 in what is now Kittitas county. The more recent discoveries of placera date from the year 1881, when the Cle Elum placera were found.

The first quartz was found by Hiram F. Smith on July 4, 1871, on the "Moses reservation," now in Okanogan county. It was at the base of Mt. Chapaka, where the district was formed, and where many miners came. Hardly had the work of development commenced before the soldiers made them leave the reservation. To this fact is ascribable the reason why, when found as far back as 1871, these valuable mines remained practically unheard of until as recently as the last four years after the Moses reservation was restored to the public domain. Ore was found in 1878 on the Peschaetin river by C. P. Culver. In 1881 the Cle Elum district was discovered, and in 1883 the first gold and silver bearing ores were found in Colville district, but it was not until 1885 that the district was brought into prominence.

Water Supply of Cities.

The Citizens' Committee of One Hundred of Oakland sent out, some time since, a number of circulars to the larger cities of the United States with a view to obtaining information as to their water supply. The questions asked were as follows:

1. Is your water supply drawn from wells, lake or stream?
2. Is water furnished you by a corporation, or does your city own the plant?
3. If water is furnished by a corporation, by whom and how often are the rates fixed?
4. If water is furnished by a corporation, what arrangements have you with them for furnishing water for public use, viz: street sprinkling, Fire Department, public buildings, etc?
5. If your city now owns its plant, but water was formerly furnished you by a corporation, what was the chief cause or causes that brought about the change?
6. Does your water require filtration, and, if filtered, by what process?
7. What proportion of your consumers use meters?
8. If city owns plant, is it a source of profit or expense?
9. Do your people appear to be satisfied with your present water service?
10. Can you send us list of rates charged or any other literature on the subject?

In response to this circular letter issued by Recording Secretary J. W. Dutton, answers were received from 172 cities, and with these answers came a mass of information pertaining to the subject, in the form of letters and reports, all of which have been carefully compiled by Prof. Frank Soule, of the State University, Corresponding Secretary of the Committee.

This compilation has not yet been published, but the following is a brief summary of the facts and figures contained in the manuscript copy now in the possession of the Committee of One Hundred.

SUMMARY.

No. of cities answering questions of committee.....	172
No. of cities owning their own water works and water service.....	120
Of these, satisfactory.....	105
Unsatisfactory (on account of quality of water).....	8
Not stated.....	7
No. of cities in which water works were controlled by private corporations.....	53
Satisfactory.....	22
Unsatisfactory.....	30

The reports from 162 cities in the East where water-meters are used are as follows:

Average minimum price per 1000 gallons.....	94c
Average maximum price per 1000 gallons.....	25c

IN OAKLAND.

Average minimum price per 1000 gallons.....	30c
Average maximum price per 1000 gallons.....	65c

In 162 Eastern cities the following are the average annual rates:

Dwellings, one family.....	\$6 35
One bath-tub.....	3 44
One horse.....	2 04
One water-closet.....	3 70
Lawn, 60x120 feet.....	1 35

In Oakland the annual average rates are as follows:

Dwellings, one family.....	\$27 60
One bath-tub.....	6 00
One horse.....	6 00
One water-closet.....	4 20
Lawn, 60x120 feet.....	39 96

Other items bear the same general ratio. Except in case of replies from private water companies themselves, the opinion is unanimous that the city should own the water works and control the service through a Board of Water Commissioners.

Since the compilation of these figures, the City Council of Oakland has reduced the rates of the company slightly, especially in the case of smaller dwellings. But in the opinion of the citizens, the rates still continue much too high. The same condition exists in a number of other towns in this State.

Assayers' Manual.

We have received from Henry Carey Baird & Co., of Philadelphia, the second American edition of the "Assayer's Manual," an abridged treatise on the doctimate examination of ores and furnace and other artificial products, by Bruno Karl. The new volume has been edited with extensive additions by F. Lynwood Garrison of Philadelphia.

While there has been but little improvement in the old fire assay methods, the advancement in wet and particularly electrolytic methods has been notable. In this particular the editor has drawn largely from a German work of Baling. A somewhat lengthy article on the dry assay of iron ores appears in the appendix of this work. The object of the "assayer's manual" is to give directions for executing doctimate tests of natural and artificial products by methods taken mostly from practice, and which are of interest especially to metallurgists and also to other technologists. The book comprises some 350 pages, and has a number of illustrations. It is clearly and plainly written, and a very useful work for any one interested in assaying any kind of ores.

Gold Bullion for Export.

To prevent gold going out of the country, Congress recently passed a law by which it is necessary to pay four cents on every \$100 worth of gold bullion for export. It has been customary to obtain good new coin or bars for export, but now they must take the coin just as it runs, abraded or not, unless a special charge is paid. The superintendent of the U. S. Assay Office at New York has received instructions from the Treasury Department authorizing him to place a charge on gold bars sufficient to pay the cost of manufacture. This cost is to be at the rate of four cents for every \$100 worth of gold, and the charge will be imposed on the gold now ordered for shipment.

It is, however, the opinion of Superintendent Mason that this small addition to the cost of gold will not be sufficient to check the exportation of the precious metal from this country when the commercial needs of other nations require such shipments and the rate of exchange permits them.

The British mints place a manufacturing charge on gold handled therein, but this has not prevented the United States from getting the gold when it was wanted and became profitable to import it. The only way the Bank of England can keep gold in that country is by advancing the rate of discount, making money so valuable there that it would not pay to export it.

The Associated Banks in New York have practically the same power if they choose to exercise it. By refusing to make discounts at low rates, the money would become more valuable at home than if sent abroad.

Cleaning Plates.

EDITORS PRESS:—I have been for some years a subscriber for the MINING AND SCIENTIFIC PRESS and would like you to give me some information about cleaning quicksilver. What is best to clean it with and not injure your plates?
J. H. S.

Deadwood, Siskiyou Co.

Mr. Denniston, the manufacturer of silver-plated amalgamating plates, gives preference in cleaning these plates to a weak solution of cyanide of potassium or a strong solution of salt and water, using a brush with each.

To insure good amalgamation, the plates must be kept clean and bright. Grease or oil of course prevent proper amalgamation. The presence of these deleterious substances should be carefully avoided, and if present must be counteracted by the introduction into the battery of a saturated solution of wood ashes. Cyanide of potassium in dilute solution is used to promote amalgamation, but the practice of using the cyanide is less common than formerly. One or two pounds will be sufficient to clean the plates of a 40-stamp mill for a year.

Some people use a solution of vinegar and salt for cleaning plates. Very dilute nitric acid is also used, the plates being at once rubbed with quicksilver after being washed with clear water.

The quicksilver itself is carefully washed and strained through a canvas bag to remove as many impurities as possible and again strained. On a small scale it can be strained by hand through a chamois bag. Of course the quicksilver, when it becomes dirty or mixed with foreign substances, must be retorted at a low temperature to thoroughly clean it.

CO-OPERATIVE EXPOSITIONS.—Two of the principal officers of the Portland (Oregon) Industrial Exposition, E. A. King, vice-president, and R. W. Mitchell, secretary, are in this city urging co-operation on the part of the Mechanics' Institute Exposition managers. It has been found that it is difficult to secure Eastern attractions of a novel character for a single exposition of four or five weeks. With two expositions, one following the other and located at different yet not conflicting points, many new features could be obtained.

THE Tacoma smelter last month turned out bullion valued at \$51,551, of which \$32,043 was silver, \$13,181 lead, and \$6326 gold. The smelting company employs 64 men, and the pay-roll for the month was \$3476.

THE Hale and Norcross Mining Company re-elected its old Board of Directors, consisting of H. M. Levy, A. K. P. Harmon, M. Hoeflich, Joseph Marks, John F. Eagan, J. B. Low and H. S. Wheeler.

Amalgamating Gold.

In describing the Idaho mill and the Grass Valley method of working gold quartz, Eggleston in his work on the "Metallurgy of Gold, Silver and Mercury in the United States," has engravings of the Attwood amalgamator and the Eureka rubber. The mill uses eight Attwood amalgamators and seven Eureka rubbers, twenty-one blanket sluices, four Knox pans and two huddle concentrators. The pulp goes from the battery into a splash box which discharges into a trough to distribute the pulp over the blanket sluices. The sluices project over a trough which connects with another five feet long, there being one for each set of two batteries on one side of the mill and four on the other, which is 18 feet long and 13 inches wide. These are filled with copper plates and discharge on a Eureka rubber.

From the constant washing of the blankets a considerable amount of material collects in the bottom of the vats used for that purpose, and when the solid material has accumulated and of proper consistency to be handled by a shovel, it is charged into an Attwood-amalgamator feeder *p*, shown in the cut. This exceedingly simple machine is shown in section and perspective in the cuts. It consists of two wooden troughs *a*, 14 inches wide, 6 inches deep and 19 inches long, which are semi-circular in shape, holding from 350 to 400 pounds of mercury each. Over the mercury a cylinder of wood *b*, 8 inches in diameter and 18 inches long, is made to revolve.

The circumference of this cylinder is divided into 12 equal parts and its length into 18. Commencing at each end with a half division, iron

automatic feeder is arranged on the top frame of the amalgamator.

The wheels *c* and *f* communicate motion to an arm *g*, which communicates with an iron lever *h*, bent at right angles and hinged at the angle. The end of this arm, to which *g* is

placed in any position in the box *p*. The screw and ratchet are regulated so as to move just fast enough to wash the pulp out of the feed-box.

The blanket washings are charged in the back of the feed-box *p*, which is 18 inches wide,

rifles, will sink to the bottom. The gold, except that contained in the pyrites or attached to small particles of ore, will be caught by the mercury of the haul or rifles, while the constant agitation of the rods on the wheels *b* will tend to keep the lighter particles of poor material in suspension. As the material which passes through this machine is the most valuable part of the ore, great care is taken, not only that the pulp shall be evenly and constantly fed, but also that the surface of the mercury is kept bright. Both that in the hauls under the wheels and in the rifles is continually watched, and cleaned as soon as its surface is no longer quite bright. These skimmings are put on one side for after-treatment. The success of the mill depends in a great measure on the care with which this work is performed. The automatic feeder does not need much watching. The water feed-pipe *e* occasionally gets stopped or impeded in its motion, but the mercury requires constant attention. Most of the gold in the mill is caught in this machine.

The object of the Eureka rubber is to clean any rusty gold; to rub off by friction any slime which may have attached itself to it, or to brighten the gold in milling operations so that it may more easily amalgamate. This rubber is used in many gold mills in this State and elsewhere.

The rubber (see cuts) is made of a cast iron box *a*, 1½ inches thick and 56 inches square and 7 inches deep, into which a false bottom 2½ inches thick is placed. This false bottom is made up of three parts: The dies *c*, made of soft wood, cut across the grain, which are 4 by 11 inches, and between which the wooden die bed-plate *b*, 3½ inches wide and 1 inch thick, and the whole width of the box is placed.

On top of this die bed-plate, the cast-iron dies *d*, which are 3½ inches wide at the bottom, 4 inches at top, and 2 inches thick, are placed, the object of the flare being to hold the under dies, *c*, in place when the surface begins to wear. The bottom of the box thus becomes a die, consisting of alternate strips of wood and iron, which are held firmly in their place by wooden strips, *e*, one inch thick let three-fourths inch into the dies and bolted to the side of the box. Over the die a wooden frame, *i*, held together by two bolts, *s*, is suspended from the top of the frame, *p*, by iron rods one-half inch in diameter. It is moved backward and forward by means of an eccentric, *n*.

To the bottom of this frame, cast-iron foot-plates *j* having six slots formed by flanges projecting 1½ inch to receive the wooden shoes, are placed. The wooden shoes *h* are 3½ inches wide and 2½ inches thick, and have iron shoes *f* 4 inches wide at the top, and 3½ inches at the bottom, and 1 inch thick fastened to them by means of sockets *g* (see perspective drawing) cast on them. Both the iron and wooden shoes *f* *h* have amalgamated copper plates at-

EUREKA RUBBER FOR CLEANING "RUSTY" GOLD.

SHOE AND DIE OF THE EUREKA RUBBER.

FEEDER FOR ATTWOOD'S AMALGAMATOR.

rods one-fourth inch in diameter and three inches long are set at right angles to the surface of the cylinder, but slightly curved at one end. They are set in quincunx, but do not touch the mercury, though they come very close to it. Two of these cylinders are set three feet apart and make 60 revolutions per minute.

The blanket washings are put in the charging-box *p*. As it is necessary that the pulp should be made to flow with the greatest regularity through the amalgamator, an ingenious

arrangement, has three holes to admit of a change of movement there, and to one of them a ratchet *i*, moving on the ratchet wheel *k*, is attached. This wheel is made to move forward, one ratchet for every revolution of *c* and *f*. Keyed on to *k*, and serving as an axis of rotation, is an iron bar *l*, with a screw-thread out of which a half nut *m*, kept in position by the counterpoise *n*, is placed; to the counterpoise lever the water feed-box is attached. By raising the counterpoise arm the pipe *e* can be

three feet three inches long and ten inches high. The pipe *e* is set so that the water will flow over the ore and wash it out into the amalgamator; it moves backward as fast as the ore is washed out. The water used for this purpose is heated to a temperature of 120 degrees to 130 degrees Fahr., as it is found that the amalgamator works better hot than cold. The washings pass through the first amalgamator, over the rifles, on to the second, and out at the discharge *t*. The heavy particles, as they pass under the wheels and over the

attached to them. The arrangement of shoes and dies is clearly seen in the perspective drawing. The rods *o* suspend the shoe frame from a movable frame *p* which is capable of adjustment by means of a screw *g* which allows the shoes and dies to be set at any distance. The eccentric wheel communicates the movement to the shaft *l* which goes across the top of the frame, makes 55 revolutions per minute, and gives a motion 4 inches backward and forward. The pulp from the Attwood amalgamator is discharged from a trough so arranged as to give an equal supply to each rubber; passing on to the rubber, it goes under the shoes and dies, and the bright surfaces are caught by the amalgamated plates,

ATTWOOD'S AMALGAMATOR FOR GOLD MILLS.

TECHNOLOGY OF ANIMAL, VEGETABLE,
AND MINERAL**FATS AND OILS AND LUBRICANTS**
—AND—
SOAP AND CANDLES.

BRANNT.—A Practical Treatise on Animal and Vegetable Fats and Oils; comprising both Fixed and Volatile Oils, their Physical and Chemical Properties and Uses. The manner of Extracting and Refining them, and Practical Rules for Testing them, as well as the Manufacture of Artificial Butter, Lubricants, including Mineral Lubricating Oils, etc., and 60 Ozonolite. Edited from the German and other sources by W. T. Brannt. 240 engravings, 730 pages, 8vo. Price.....\$7.50

BRANNT.—A Practical Treatise on the Manufacture of Soap and Candles, comprising the Chemistry, the Raw Materials, the Machinery and Utensils, and Various Processes of Manufacture, including a great variety of formulae. Edited chiefly from the German by W. T. Brannt. 163 engravings, 677 pages, 8vo. Price.....\$7.50

CREW.—A Practical Treatise on Petroleum; comprising its Origin, Geology, Geographical Distribution, History, Chemistry, Mining, Technology, Uses and Transportation; together with a description of Gas Wells, the Application of Gas as Fuel, etc. By Benj. J. Crew. With an Appendix on the Oil Regions and the Geology of Natural Gas in Pennsylvania and New York. By Chas. A. Ashburner. 70 engravings and two plates, 508 pages, 8vo. Price.....\$5.00

CRISTIANI.—A Technical Treatise on Soap and Candles. By R. S. Cristiani. 176 engravings, 581 pages, 8vo. Price.....\$10.00

63 & 65 First St., cor. Mission, San Francisco.

We would call the attention of Assayers, Chemists, Mining Companies, Milling Companies, Prospectors, etc., to our full stock of Balances, Furnaces, Muffles, Crucibles, Sootifiers, etc., including, also, a full stock of Chemicals.

Having been engaged in furnishing these supplies since the first discovery of mines on the Pacific Coast, we feel confident from our experience we can well suit the demand for these goods, both as to quality and price.

Agents for the Morgan Crucible Co., Battersea, England. Also for E. G. Dennison's Silver Plated Amalgam Plates. The plates of this well-known manufacturer are thoroughly reliable, and full weight of Silver guaranteed. Orders taken at his lowest prices. Our Illustrated Catalogue and Assay Tables sent free on application.

Gas and Gasoline Engines.

Pacific Coast inventors have done much toward the perfection of motors of this class, particularly in the way of igniting the charge of gas and air by means of a small electric battery, the greatest difficulties to overcome being the constant burning out of the electrodes and consequent necessity of replacing them every day or two; and further, the leakage and frequent cleaning and overhauling required by the check-valves for inlet of gas and "poppet" valves for exhaust.

Henceforth the celebrated and high-priced Otto gas engine (invented principally in Germany) has been the only motor of this character to overcome the defects named—their igniting device being by means of a small gas-jet flame, and their gas inlet by means of an elaborate but positive slide cut-off valve. However, the Pacific Coast now comes to the front with a gas and gasoline engine, which, for perfection and simplicity of mechanical detail and economical cost of operation, is beyond question a great achievement in the way of motive-power. The working parts are all regulated from the outside. The electrodes are substantial, sure fire, and will last for many months, and can then be replaced at a trifling cost. But the main feature is a simple combination of the gas inlet and exhaust in one positive cut-off slide valve that will not leak, and requires no attention whatever, as it is self-cleaning and therefore will not cut with grit or carbon.

This engine is also endowed with a very simple and effective gas generator (for gasoline gas) situated entirely out of the way in the base of the engine and absolutely safe, and its gas regulator gives the highest economy. We might mention many other points, such as an easy way of starting by means of a patent safety crank; a special electric battery that will enable engine to run day and night on one switch, etc., with a high degree of substantial mechanical completeness in every detail. Readers who may wish further particulars are referred to the Electric Vapor Engine Co., No. 213 California St., San Francisco. They make a specialty of pumping plants, launchers, etc., driven by either single or double-acting engines.

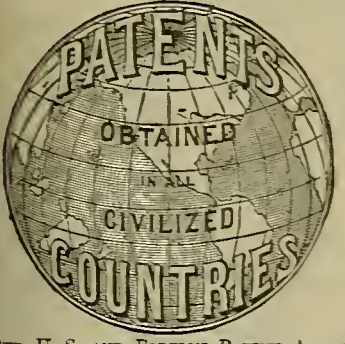

Easy Binder.

Dewey's patent elastic binder, for periodicals, music and other printed sheets, is the handiest, best and cheapest of all economical and practical file binders. Newspapers are quickly placed in it and held neatly, as in a cloth-bound book. It is durable and so simple a child can use it. Price, size of Mining and Scientific Press, Rural Press, Watchman, Fraternal Record, Masonic Record, Harper's Weekly, and Scientific American, 75 cents; post age, 10 cents. Postpaid to subscribers of this paper, 50 cents. Send for illustrated circular. Agents wanted.

Don't Fail to Write.

Should this paper be received by any subscriber who does not want it, or beyond the time he intends to pay for it, let him not fail to write us direct to stop it. A postal card (costing one cent only) will suffice. We will not knowingly send the paper to any one who does not wish it, but if it is continued, through the failure of the subscriber to notify us to discontinue it, or some irresponsible party requested to stop it, we shall positively demand payment for the time it is sent. LOOK CAREFULLY AT THE LABEL ON YOUR PAPER.

Dewey & Co.'s Scientific Press
Patent Agency.

OUR U. S. AND FOREIGN PATENT AGENCY presents many and important advantages as a Home Agency over all others, by reason of long establishment, great experience, thorough system, intimate acquaintance with the subjects of inventions in our own community, and our most extensive law and reference library, containing official American and foreign reports, files of scientific and mechanical publications, etc. All worthy inventions patented through our Agency will have the benefit of an illustration or a description in the MINING AND SCIENTIFIC PRESS. We transact every branch of Patent business, and obtain Patents in all countries which grant protection to inventors. The large majority of U. S. and Foreign Patents issued to inventors on the Pacific Coast have been obtained through our Agency. We can give the best and most reliable advice as to the patentability of new inventions. Our prices are as low as any first-class agencies in the Eastern States, while our advantages for Pacific Coast inventors are far superior. Advice and Circulars free.

Complimentary Samples.

Persons receiving this paper marked are requested to examine its contents, terms of subscription, and give it their own patronage, and, as far as practicable, aid in circulating the journal, and making its value more widely known to others, and extending its influence in the cause it faithfully serves. Subscription rate, \$3.00 a year. Extra copies mailed for 10 cents, if ordered soon enough. If already a subscriber, please show the paper to others.

Back Files of the MINING AND SCIENTIFIC PRESS (on bound) can be had for \$3 per volume of six months. Per year (two volumes) \$5. Inserted in Dewey's patent binder, 50 cents additional per volume.

Assessment Notices.

CRESCENT MILL & MINING COMPANY.

Location of principal place of business, San Francisco, California. Location of works, Crescent Mill, Plumas County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on Friday, the 28th day of February, 1891, an assessment (No. 5) of Twenty-five cents (\$25) per share was levied upon the Capital Stock of the Corporation, payable immediately in United States gold coin to the Secretary at the office of the Company, No. 319 Pine Street, Room 40, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 6th day of April, 1891, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on MONDAY, the 4th day of MAY, 1891, to pay the delinquent assessment, together with the costs of advertising and expenses of sale.

By order of the Board of Directors,
J. H. ISHAM, Secretary,
Office, No. 319 Pine Street, Room 40, San Francisco, California.

DELINQUENT SALE NOTICE.

GRAY EAGLE MINING COMPANY—Loca-

tion of principal place of business, San Francisco, California. Location of works, Placer county, California.

Notice is hereby given, that there are delinquent upon the following described stock, on account of Assessment (No. 22) levied on the 4th day of February, 1891, the several amounts set opposite the names of the respective shareholders, as follows:

Names.	No. Cert.	No. Shares.	Am't.
Barrows, A. W., Trustee.	353	271	\$ 4.13
Francis, H. L., Trustee.	444	1,500	45.00
Horton, I. R., Trustee.	365	2,500	75.00
Lane, Mrs. Sarah, Trustee.	383	250	6.00
Stout, C. S., Trustee.	477	953	28.59
Searles, W. A., Trustee.	315	1,000	30.00

And in accordance with law, and an order of the Board of Directors, made on the 4th day of February, 1891, so many shares of each parcel of such stock as may be necessary, will be sold at public auction, at the office of the Company, Room 11, No. 303 California street, San Francisco, California, on MONDAY, the 30th day of March, 1891, at the hour of one (1) o'clock P. M. of said day, to pay said delinquent assessment thereon, together with costs of advertising and expenses of the sale.

A. W. BARROWS, Secretary pro tem.
Office, Room 11, No. 303 California street, San Francisco, California.

The Woodbury Ore Concentrator.

On this page are presented engravings of the Woodbury ore concentrator and of the improved concentrator belt used on the machine. To give this concentrator more capacity than those of the ordinary form, it is constructed to carry 13 narrow belts, and by dividing the pulp equally upon each belt, they prevent the pulp from running from one side to the other, or to in any way interfere with the working of any part of the pulp not allotted to its particular place. The belts are made perfectly smooth on the surface, the inventor believing that way of using belts is better for fine and close work than any corrugations. Corrugated surface belts can be used, however, if preferred.

The main frame of the concentrator is made of iron, giving it stability and durability. The main shaft is two-inch steel; the main boxes are self-oiling, and the connecting-boxes are large and self-oiling. It requires less than one-half the room in the mill of the ordinary machines, and it is claimed will run with much less power, water and attention.

Mr. Woodbury states that this concentrator will work from 12 to 15 tons of ore, which is much beyond the capacity of the ordinary belt machine. The narrow belts run each on a separate crown on the roller, so that there is no possibility of their getting out of line, and no adjustment is required after they are once started. A revolving feed bowl distributes to each belt its exact proportion of sand, water, and sulphurets, thereby largely increasing the capacity of the machine.

The belt used is patented by the same inventor. It is constructed with edges corrugated for the purpose of elongating the edge at the top, and gradually diminishing toward the main part of the belt. This improvement prevents the edges from cracking, as the edges have only to straighten out and not stretch as they pass around the drums, and there is, therefore, no strain on the edges.

Mr. Woodbury says that this machine does not require an expert to run it. A man of ordinary intelligence can learn to do good work with it in a few hours. Forty-five of these machines have been put in operation in

THE WOODBURY ORE CONCENTRATOR.

WOODBURY CONCENTRATOR BELT.

the last 18 months, each in every case working for five stamps. The machine costs, shipped, \$575. George E. Woodbury, 213-217 Front street, in this city, is the inventor and manufacturer.

The "Vulcan" Wire Ropeway.

Valuable improvements have been made during the past few years in the details of wire ropeways for transporting ore, cordwood and other material. In mountainous districts, where roads are impracticable, the wire ropeway may be regarded as a necessity, as the contour of the ground offers no impediment—the ropeway "leaping from hill to hill," and often, unsupported, crossing chasms many hundred feet in depth. The Vulcan Wire ropeway system is an improved form, the details of which are the result of experience. The accompanying engravings show the construction of the improved ropeway.

An endless wire rope is supported at inter-

vals (varying according to the nature of the ground from 150 to 2000 feet) on grooved supporting sheaves which are secured to the ends of a cross-arm elevated on a suitable supporting structure or tower. The rope passes around horizontal grip-sheaves placed at each extremity of the ropeway and over the supporting sheaves. The grip-sheave is so constructed as to prevent the rope from slipping and is furnished with a suitable brake to regulate the speed. By means of the grip-sheaves power can be transmitted to or from the traveling rope.

To one of the terminal structures is attached a counter-weight that counterbalances the weight of the load carried, takes up the stretch of the rope, and likewise provides for any contraction or expansion of the rope, caused by change of temperature.

The conveyors or carriers (which vary in shape according to the character of the material to be transported) are loaded with about 125 pounds—the loading and unloading being done

while the rope is in motion. These conveyors are attached to hangers that are suspended from the projecting shafts of the clips which are inserted in the rope at suitable distances, to correspond to the quantity of material to be delivered per day.

Thus it will be seen that when the rope is set in motion it will carry with it the loaded conveyors at such rate of speed as may be determined most suitable, usually about 200 feet per minute. The conveyors are easily loaded or unloaded as they pass by, which can be done at any point on the line. These conveyors may be loaded automatically, if so desired. The unloading is always done automatically.

When the point of discharge is lower than the point of loading, equivalent to a grade of one in seven (or an inclination of eight degrees), the ropeway will run by gravitation. When the angle of descent is less than eight degrees, power of some kind must be employed to run the rope, and may be applied at any part of the line.

When the angle of descent is sufficient, there can be carried back to the mine, or to the head of ropeway system, various material, supplies, etc., or the surplus power may be transmitted, by suitable attachments, to mill machinery.

Fig. 1 of the accompanying engravings is a general view of the whole system. Fig. 2 is a supporting or station sheave and stand. Fig. 3 is a guide sheave and stand. These sheaves are made from 22 to 36 inches diameter, and if desired are furnished with metal line bushings, dispensing with the use of oil. The sheaves are

The New Land Law.

Text of an Important Act.

Be it enacted, etc., That an Act entitled "An Act to amend an Act entitled 'An Act to encourage the growth of timber on the Western prairies,'" approved June 14, 1878, and all laws supplementary thereto or amendatory thereof, be, and the same are, hereby repealed: *Provided*, That this repeal shall not affect any valid rights heretofore accrued or accruing under said laws, but all bona-fide claims lawfully initiated before the passage of this Act may be perfected upon due compliance with law, in the same manner, upon the same terms and conditions, and subject to the same limitations, forfeitures and contests as if this Act had not been passed: *And provided further*, That the following words of the last clause of Section 2 of said Act, namely, "That not less than twenty-seven hundred trees were planted on each acre," are hereby repealed: *And provided further*, That, in computing the period of cultivation, the time shall run from the date of the entry if the necessary acts of cultivation were performed within the proper time: *And provided further*, That the preparation of the land and the planting of trees shall be construed as acts of cultivation, and the time authorized to be so employed and actually employed shall be computed as a part of the eight years of cultivation required by statute: *Provided*, That any person who has made entry of any public lands of the United States under the timber culture laws, and who has for a period of four years in good faith complied with the provisions of said laws and who is an actual bona-fide resident of the State or Territory in which said land is located, shall be entitled to make final proof thereon, and acquire title to the same, by the payment of \$1.25 per acre for such tract, under such rules and regulations as shall be prescribed by the Secretary of the Interior, and registers and receivers shall be allowed the same fees and compensation for final proofs in timber-culture entries as is now allowed by law in homestead entries: *And provided further*, That no land acquired under the provisions of this Act shall in any event become liable to the satisfaction of any debt or debts contracted prior to the issuing of the final certificate therefor.

DESERT LANDS.

Sec. 2. That an Act to provide for the sale of desert lands in certain States and Territories, approved March 3, 1877, is hereby amended by adding thereto the following sections:

"Sec. 4. That at the time of filing the declaration herebefore required the party shall also file a map of said land, which shall exhibit a plan of showing the mode of contemplated irrigation, and which plan shall be sufficient to thoroughly irrigate and reclaim said land and prepare it to raise ordinary agricultural crops, and shall also show the source of the water to be used for irrigation and reclamation. Persons entering or proposing to enter separate sections, or fractional parts of sections, of desert lands may associate together in the construction of canals and ditches for irrigating and reclaiming all of said tracts, and may file a joint map or maps showing their plan of internal improvements.

"Sec. 5. That no land shall be patented to any person under this Act unless he or his assignors shall have expended in the necessary irrigation, reclamation and cultivation thereof, by means of main canals and branch ditches, and in permanent improvements upon the land, and in the purchase of water rights for the irrigation of the same, at least \$3 per acre of whole tract reclaimed and patented in the manner following: Within one year after making entry for such tract of desert land as aforesaid, the party so entering shall expend not less than \$1 per acre for the purposes aforesaid; and he shall in like manner expend the sum of \$1 per acre during the second and also during the third year thereafter, until the sum of \$3 per acre is so expended. Said party shall file during each year with the Register proof, by the affidavits of two or more credible witnesses, that the full sum of \$1 per acre has been expended in such necessary improvements during such year, and the manner in which expended, and at the expiration of the third year a map or plan showing the character and extent of such improvements. If any party who has made such application shall fail during any year to file the testimony aforesaid, the lands shall revert to the United States and the 25 cents advanced payment shall be forfeited to the United States and the entry shall be canceled. Nothing herein contained shall prevent a claimant from making his final entry and receiving his patent at an earlier date than herebefore prescribed, provided that he then makes the required proof of reclamation to the aggregate extent of \$3 per acre: *Provided*, That proof be further required of the cultivation of one-eighth of the land.

"Sec. 6. That this Act shall not affect any valid rights heretofore accrued under said Act of March 3, 1877, but all bona-fide claims heretofore lawfully initiated may be perfected, upon due compliance with the provisions of said Act, in the same manner, upon the same terms and conditions, and subject to the same limitations, forfeitures and contests as if this Act had not been passed; or said claims, at the option of the claimant, may be perfected and patented under the provisions of said Act, as amended by this Act, so far as applicable; and all Acts and parts of Acts in conflict with this Act are hereby repealed.

"Sec. 7. That any time after filing the declaration, and within the period of four years thereafter, upon making satisfactory proof to the register and the receiver of the reclamation and cultivation of said land to the extent and cost and in the manner aforesaid, and substantially in accordance with the plans herein provided for, and that he or she is a citizen of the United

States, and upon payment to the receiver of the additional sum of \$1 per acre for said land, a patent shall issue therefor to the applicant or his assigns; but no person or association of persons shall hold by assignment or otherwise, prior to the issue of patent, more than 320 acres of such arid or desert lands, but this section shall not apply to entries made or initiated prior to the approval of this Act: *Provided, however*, That additional proofs may be required at any time within the period prescribed by law, and that the claims or entries made under this or any preceding Act shall be subject to contest, as provided by the law relating to homestead cases, for illegal inception, abandonment or failure to comply with the requirements of law, and upon satisfactory proof thereof shall be canceled and the lands and moneys paid therefor shall be forfeited to the United States.

"Sec. 8. That the provisions of the Act to which this is an amendment, and the amendments thereto, shall apply to and be in force in the State of Colorado, as well as the States named in the original Act; and no person shall be entitled to make entry of desert land except he be a resident citizen of the State or Territory in which the land sought to be entered is located."

PRE-EMPTION OF PUBLIC LANDS.

Sec. 3. That Section 2238 of the Revised Statutes be amended so as to read as follows:

"Sec. 2238. Any bona-fide settler under the pre-emption, homestead, or other settlement law shall have the right to transfer, by warranty against his own acts, any portion of his claim for church, cemetery, or school purposes, or for the right of way of railroads, canals, reservoirs, or ditches for irrigation or drainage across it; and the transfer for such public purposes shall in no way vitiate the right to complete and perfect the title of his claim."

Sec. 4. That Chapter 4 of Title XXXII, excepting Sections 2275, 2276, 2286 of the Revised Statutes of the United States, and all other laws allowing pre-emption of the public lands of the United States, are hereby repealed, but all bona-fide claims lawfully initiated before the passage of this Act, under any of said provisions of law so repealed, may be perfected upon due compliance with law in the same manner, upon the same terms and conditions, and subject to the same limitations, forfeitures and contests as if this Act had not been passed.

REVISED STATUTES AMENDED.

Sec. 5. That Sections 2289 and 2290, in said chapter numbered 5 of the Revised Statutes, be and the same are hereby amended so that they shall read as follows:

"Sec. 2289. Every person who is the head of a family, or who has arrived at the age of twenty-one years, and is a citizen of the United States, or who has filed his declaration of intention to become such, as required by the naturalization laws, shall be entitled to enter one-quarter section, or a less quantity of unappropriated public lands, to be located in a body in conformity to the legal subdivisions of the public lands; but no person who is the proprietor of more than 160 acres of land in any State or Territory shall acquire any right under the homestead law. And every person owning and residing on land may, under the provisions of this section, enter other land lying contiguous to his land, which shall not, with the land so already owned and occupied, exceed in the aggregate 160 acres.

"Sec. 2290. That any person applying to enter land under the preceding section shall first make and subscribe before the proper officer and file in the proper land office an affidavit that he or she is the head of a family, or is over twenty-one years of age, and that such application is honestly and in good faith made for the purpose of actual settlement and cultivation, and not for the benefit of any other person, persons, or corporations, and that he or she will faithfully and honestly endeavor to comply with all the requirements of law as to settlement, residence and cultivation necessary to acquire title to the land applied for; that he or she is not acting as agent of any person, corporation, or syndicate in making such entry, nor in collusion with any person, corporation or syndicate, to give them the benefit of the land entered, or any part thereof, or the timber thereon; that he or she does not apply to enter the same for the purpose of speculation, but in good faith to obtain a home for himself or herself, and that he or she has not directly or indirectly made, and will not make, any agreement or contract in any way or manner, with any person or persons, corporation or syndicate whatsoever, by which the title which he or she might acquire from the Government of the United States should inure, in whole or in part, to the benefit of any person, except himself or herself; and upon filing such affidavit with the register or receiver on payment of \$5 when the entry is not more than 80 acres, and on payment of \$10 when the entry is for more than 80 acres, he or she shall thereupon be permitted to enter the amount of land specified."

Sec. 6. That Section 2301 of the Revised Statutes be amended so as to read as follows:

"Sec. 2301. Nothing in this chapter shall be so construed as to prevent any person who shall hereafter avail himself of the benefits of Section 2289 from paying the minimum price for the quantity of land so entered at any time after the expiration of fourteen calendar months from the date of such entry, and obtaining a patent therefor, upon making proof of settlement and of residence and cultivation for such period of fourteen months; and the provision of this section shall apply to lands on the ceded portion of the Sioux reservation, by Act approved March 2, 1889, in South Dakota, but shall not relieve said settlers from any payments now required by law."

CLERICAL ERRORS.

Sec. 7. That whenever it shall appear to the Commissioner of the General Land Office that a

clerical error has been committed in the entry of any of the public lands, such entry may be suspended upon proper notification to the claimant, through the local land office, until the error has been corrected; and all entries made under the pre-emption, homestead, desert-land or timber-culture laws, in which final proof and payment may have been made and certificates issued, and to which there are no adverse claims originating prior to final entry, and which have been sold or incumbered prior to the 1st day of March, 1888, and after final entry, to bona-fide purchasers or incumbents, for a valuable consideration, shall, unless upon an investigation by a Government agent, fraud on the part of the purchaser has been found, be confirmed and patented upon presentation of satisfactory proof to the Land Department of such sale or incumbrance: *Provided*, That after the lapse of two years from the date of the issuance of the receiver's receipt upon the final entry of any tract of land under the homestead, timber-culture, desert-land or pre-emption laws, or under this Act, and when there shall be no pending contest or protest against the validity of such entry, the entryman shall be entitled to a patent conveying the land by him entered, and the same shall be issued to him; but this proviso shall not be construed to require the delay of two years from the date of said entry before the issuing of a patent therefor.

SUITS FOR ANNULLMENT.

Sec. 8. That suits by the United States to vacate and annul any patent heretofore issued shall only be brought within five years from the passage of this Act, and suits to vacate and annul patents hereafter issued shall only be brought within six years after the date of the issuance of such patents. And in the States of Colorado, Montana, Idaho, North Dakota and South Dakota, Wyoming and in the district of Alaska, and the gold and silver regions of Nevada, and the Territory of Utah, in any criminal prosecution or civil action by the United States for a trespass on such public timber lands or to recover timber or lumber cut thereon, it shall be a defense if the defendant shall show that the said timber was so cut or removed from the timber lands for use in such State or Territory by a resident thereof for agricultural, mining, manufacturing or domestic purposes, and has not been transported out of the same; but nothing herein contained shall apply to operate to enlarge the right of any railway company to cut timber on the public domain: *Provided*, That the Secretary of the Interior may make suitable rules and regulations to carry out the provisions of this section.

Sec. 9. That hereafter no public lands of the United States, except abandoned military or other reservations, isolated and disconnected fractional tracts authorized to be sold by Section 2455 of the Revised Statutes, and mineral and other lands the sale of which at public auction has been authorized by Acts of Congress of a special nature having local application, shall be sold at public sale.

Sec. 10. That nothing in this Act shall change, repeal, or modify any agreements or treaties made with any Indian tribes for the disposal of their lands, or of land ceded to the United States to be disposed of for the benefit of such tribes, and the proceeds thereof to be placed in the Treasury of the United States; and the disposition of such lands shall continue in accordance with the provisions of such treaties or agreements, except as provided in Section 5 of this Act.

ALASKA LANDS.

Sec. 11. That until otherwise ordered by Congress, lands in Alaska may be entered for townsite purposes, for the several use and benefit of the occupants of such townsites, by such trustee or trustees as may be named by the Secretary of the Interior for that purpose, such entries to be made under the provisions of Section 2387 of the Revised Statutes as near as may be; and when such entries shall have been made the Secretary of the Interior shall provide by regulation for the proper execution of the trust in favor of the inhabitants of the townsite, including the survey of the lands into lots, according to the spirit and intent of said Section 2387 of the Revised Statutes, whereby the same results would be reached as though the entry had been made by a County Judge and the disposal of the lots into such townsite and the proceeds of the sale thereof had been prescribed by the legislative authority of a State or Territory: *Provided*, That no more than 640 acres shall be embraced in one townsite entry.

Sec. 12. That any citizen of the United States twenty-one years of age, and any association of such citizens, and any corporation incorporated under the laws of the United States or of any State or Territory of the United States, now authorized by law to hold lands in the Territories, now or hereafter in possession of and occupying public lands in Alaska for the purpose of trade or manufactures, may purchase not exceeding 160 acres, to be taken as near as practicable in a square form, of such land at \$2.50 per acre: *Provided*, That in case more than one person, association or corporation shall claim the same tract of land, the person, association or corporation having the prior claim by reason of possession and continued occupation shall be entitled to purchase the same; but the entry of no person, association or corporation shall include improvements made by or in possession of another prior to the passage of this Act.

Sec. 13. That it shall be the duty of any person, association or corporation entitled to purchase land under this Act to make an application to the United States Marshal, *ex-officio* Surveyor-General of Alaska, for an estimate of the cost of making a survey of the lands occupied by such person, association or corporation, and the cost of the clerical work necessary to be done in the office of the said United States Marshal, *ex-officio* Surveyor-General; and on

the receipt of such estimate from the United States Marshal, *ex-officio* Surveyor-General, the said person, association or corporation shall deposit the amount in a United States depository, as he is required by Section numbered 2401, Revised Statutes, relating to deposits for surveys.

That on the receipt by the United States Marshal, *ex-officio* Surveyor-General, of the said certificates of deposit, he shall employ a competent person to make such survey, under such rules and regulations as may be adopted by the Secretary of the Interior, who shall make his return of his field notes and maps to the office of the said United States Marshal, *ex-officio* Surveyor-General; and the said United States Marshal, *ex-officio* Surveyor-General, shall cause the said field notes and plats of such survey to be examined, and, if correct, approve the same, and shall transmit certified copies of such maps and plats to the office of the Commissioner of the General Land Office.

That when the said field notes and plats of said survey shall have been approved by the said Commissioner of the General Land Office, he shall notify such person, association, or corporation, who shall then, within six months after such notice, pay to the United States Marshal, *ex-officio* Surveyor-General, for such land, and patent shall issue for the same.

Sec. 14. That none of the provisions of the last two preceding sections of this Act shall be so construed as to warrant the sale of any lands belonging to the United States which shall contain coal or the precious metals, or any townsite, or which shall be occupied by the United States for public purposes, or which shall be reserved for such purposes, or to which the natives of Alaska have prior rights by virtue of actual occupation, or which shall be selected by the United States Commissioner of Fish and Fisheries on the islands of Kodiak and Afognak for the purpose of establishing fish-culture stations. And all tracts of land not exceeding 640 acres in any one tract now occupied by missionary stations in the said district of Alaska are hereby excepted from the operation of the last three preceding sections of this Act. No portion of the islands of the Pribylov group or the seal islands of Alaska shall be subject to sale under this Act; and there shall be reserved in all patents issued under the provisions of the last two preceding sections, the right of the United States to regulate the taking of salmon and to do all things necessary to protect and prevent the destruction of salmon in all the waters of the lands granted frequented by salmon.

Sec. 15. That until otherwise provided by law, the body of lands known as Annette islands, situated in Alexander Archipelago in South-eastern Alaska, on the north side of Dixon's entrance, be, and the same is hereby, set apart as a reservation for the use of the Metlakatla Indians, and those people known as Metlakatla natives, who have recently emigrated from British Columbia to Alaska, and such other Alaskan natives as may join them, to be held and used by them in common, under such rules and regulations and subject to such restrictions as may be prescribed from time to time by the Secretary of the Interior.

MINERAL LANDS.

Sec. 16. That townsite entries may be made by incorporated towns and cities on the mineral lands of the United States, but no title shall be acquired by any such towns or cities to any vein of gold, silver, cinnabar, copper or lead, or to any valid mining claim or possession held under existing law. When mineral veins are possessed within the limits of an incorporated town or city, and such possession is recognized by local authority or by the laws of the United States, the title of town lots shall be subject to such recognized possession and the necessary use thereof, and when entry has been made or patent issued for such townsites to such incorporated town or city, the possessor of such mineral vein may enter and receive patent for such mineral vein and the surface ground appertaining thereto: *Provided*, That no entry shall be made by such mineral-vein claimant for surface ground where the owner or occupier of the surface ground shall have had possession of the same before the inception of the title of the mineral-vein applicant.

RESERVOIR SITES.

Sec. 17. That reservoir sites located or selected and to be located and selected under the provisions of "An Act making appropriations for sundry civil expenses of the Government for the fiscal year ending June 30, 1889, and for other purposes," and amendments thereto, shall be restricted to and shall contain only so much land as is actually necessary for the construction and maintenance of reservoirs; excluding so far as practicable lands occupied by actual settlers at the date of the location of said reservoirs, and that the provision of "An Act making appropriations for sundry civil expenses of the Government for the fiscal year ending June 30, 1891, and for other purposes," which reads as follows, namely: "No person who shall, after the passage of this Act, enter upon any of the public lands with a view to occupation, entry or settlement under any of the land laws, shall be permitted to acquire title to more than 320 acres in the aggregate under all said laws," shall be construed to include in the maximum amount of lands the title to which is permitted to be acquired by one person only agricultural lands, and not to include lands entered or sought to be entered under mineral land laws.

Sec. 18. That the right of way through the public lands and reservations of the United States is hereby granted to any canal or ditch company formed for the purpose of irrigation and duly organized under the laws of any State or Territory which shall have filed or may hereafter file, with the Secretary of the Interior a copy of its articles of incorporation, and due proofs of its organization under the same,

to the extent of the ground occupied by the water of the reservoir, and of the canal and its laterals, and fifty feet on each side of the marginal limits thereof; also the right to take from the public lands adjacent to the line of the canal or ditch, material, earth and stone necessary for the construction of such canal or ditch: *Provided*, That no such right of way shall be so located as to interfere with the proper occupation by the Government of any such reservation; and all maps of location shall be subject to the approval of the department of the Government having jurisdiction of such reservation, and the privilege herein granted shall not be construed to interfere with the control of water for irrigation and other purposes under authority of the respective States or Territories.

Sec. 19. That any canal or ditch company desiring to secure the benefits of this Act shall, within twelve months after the location of ten miles of its canal, if the same be upon surveyed lands, and if upon unsurveyed lands, within twelve months after the survey thereof by the United States, file with the Register of the Land Office for the district where such land is located a map of its canal or ditch or reservoir; and upon the approval thereof by the Secretary of the Interior the same shall be noted upon the plats in said office, and thereafter all such lands over which such rights of way shall pass shall be disposed of subject to such right of way. Whenever any person or corporation, in the construction of any canal, ditch or reservoir, injures or damages the possession of any settler on the public domain, the party committing such injury or damage shall be liable to the party injured for such injury or damage.

Sec. 20. That the provisions of this Act shall apply to all canals, ditches or reservoirs heretofore or hereafter constructed, whether constructed by corporations, individuals or associations of individuals, on the filing of the certificates and maps herein provided for. If such ditch, canal or reservoir has been or shall be constructed by an individual or association of individuals, it shall be sufficient for such individual or association of individuals to file with the Secretary of the Interior, and with the Register of the Land Office where such land is located, a map of the line of such canal, ditch or reservoir, as in case of a corporation, with the name of the individual owner or owners thereof, together with the articles of association, if any there be. Plats heretofore filed shall have the benefits of this Act from the date of their filing, as though filed under it: *Provided*, That if any section of said canal or ditch shall not be completed within five years after the location of said section, the rights herein granted shall be forfeited as to any uncompleted section of said canal, ditch or reservoir to the extent that the same is not completed at the date of the forfeiture.

Sec. 21. That nothing in this Act shall authorize such canal or ditch company to occupy such right of way except for the purpose of said canal or ditch, and then only so far as may be necessary for the construction, maintenance and care of said canal or ditch.

Sec. 22. That the section of land reserved for the benefit of the Dakota Central Railroad Company on the west bank of the Missouri river, at the mouth of Bad river, as provided by Section 16 of "An Act to divide a portion of the reservation of the Sioux nation of Indians in Dakota into separate reservations, and to secure the relinquishment of the Indian title to the remainder, and for other purposes," approved March 2, 1889, shall be subject to entry under the townsite law only.

Sec. 23. That in all cases where second entries of land on the Osage Indian Trust and diminished reserve lands in Kansas, to which at the time there were no adverse claims, have been made, and the law complied with as to residence and improvement, said entries be, and the same are hereby confirmed, and in all cases where persons were actual settlers and residing upon their claims upon said Osage Indian trust and diminished reserve lands in the State of Kansas on the 9th day of May, 1872, and who have made subsequent preemption entries either upon public or upon said Osage Indian trust and diminished reserve lands, upon which there were no legal prior adverse claims at the time, and the law complied with as to settlement, said subsequent entries be and the same are hereby confirmed.

Sec. 24. That the President of the United States may from time to time set apart and reserve, in any State or Territory having public land hearing forests, any part of the public lands wholly or in part covered with timber or undergrowth, whether of commercial value or not, as public reservations; and the President shall, by public proclamation, declare the establishment of such reservations and the limits thereof.

THE FISH COMMISSION.—Fish Commissioner Joseph D. Redding states that to overcome the growing scarcity of salmon the Commission will have to stock the streams with 3,000,000 salmon fry and will establish a hatchery on the San Francisco peninsula. At present there are only two salmon hatcheries, one at Lake Tahoe and the other in Shasta county.

IN REMOVING DEPOSIT AND SEDIMENT from tubular boilers, the usual holes should be often opened and all collection removed from over the fire. Also, when boilers are fed in front and blow off through the same pipe, the collection of mud or sediment in the rear end should be often removed.

COPPER STEEL is a new alloy of steel containing about 12 per cent of copper. Such alloys as low as four per cent of copper promise to become quite useful in the arts. But too little is known as yet to give any definite idea of the comparative value of such alloys.

Old-Time Reminiscences—Senator Hearst.

EDITORS PRESS:—Do I know Senator Hearst? asked a friend. Yes; better than his son knows him. Why, I am the individual who first hauled George up into the light of business life, and hereby hang one of many tales I can tell of my old friend. I'll only give you one now.

In the latter part of 1850, in consequence of my mining experience on Lake Superior, I was consulted by a friend living in Sacramento as to milling of gold, etc., he stating at the same time that he had invested a good deal of money in a mill in Nevada Co., and that they had just found out they had no mine. But, says my friend, there is a good mine up there belonging to a lot of Missouri boys, and that a young fellow by the name of George Hearst was working there. The object of the talk was, my friend wanted me to go and see what could be done with these Missourians, by way of getting their mine. Under certain considerations I consented to go, and had a *carte blanche* to do what I thought best. I started for Nevada, arrived the following day, and on inquiry found "George Hearst" was well known, but he was two miles off, over at Gold Flat. George always was one of those genial souls who once known would ever be remembered, liked and accommodated. Notwithstanding it was late in the afternoon, I started, and followed the trail shown me until the place was found. To a man at the windlass I asked, "Is there a Mr. Hearst here?" "George Hearst? Yes; there he's down the shaft. Do you want to see him?" Answering that I did, he hallooed out, "George, there's a man here wants to see you." "All right, haul me up," says George, and so the man tugged at the windlass. As George always was weighty on a pull, I gave a hand, and up he came. Landed, there stood before me a tall, spare, regular New Madrid Missourian in his shirt-sleeves, and having on the regulation brown Kentucky-jeans pants, roughly tucked in his boots. He was as true a California, old-time miner as could be found. I can see him now, and I don't not, were he living, but he would give more for a good oil-painting of himself as he then stood than he has since given for the richest piece of his present gallery. I introduced myself, and, to make things easy, half-way broached the business I was on. "Well, Bill," says George to the man at the windlass, "goes we'll quit; worked enough for one day, anyhow." (George never was much on the hard work; prospecting around was his forte, looking for big strikes that others could work at. He has kept this up ever since.)

"Come over to the cabin," says George to me, "and see the boys. You will have to stay all night. Guess we can fix to have you bunk with some of us." (There never was anything mean about George; he naturally had a kindly heart.) After a parley, I consented to accept the invitation, and off we posted to the cabin—a regular old-time miners' log-cabin, where all the light there was in daytime came in at the door and down the chimney. Soon, one by one, the "Missouri boys" began to come in from their labors of sluicing and various mining work.

All were partners in receipts, expenditures, and possessions. Of course I was introduced, and by the time supper was ready, they numbered some nine. Lord! thinks I, nine men to barter for a mine. It looked dubious. After supper we all got circled round the big fireplace, and the day's doings were talked over. No lamps or candles were required; the snapping fire gave light enough.

The comfort of these old log cabins, none but the pioneer can appreciate. In them there were more joyous hearts—more solid, robust health, more real mental and physical comfort, than are to be found in gilded palaces of the present. Not only this, but you could always find in them brains—men of education, of nerve—men who thought, and men who dared to do. Gold warmed the blood and brain to their greatest power, and there was plenty of gold. None but he who passed through the fire of these spirited times can understand the life and light of a home in the old log cabin of "49 and '50." But to our story: Our Missouri boys were all a light-hearted, jolly set. George, whom I considered was captain of the crowd, finally brought the business before the house (his first experience in senatorial duties), but as you may suppose, there was a good deal of doubting—they did not know who I was, and to do as I proposed, why, they did not know about it, etc., etc., and then they would start off talking about old Missouri. Finally I concluded to drop the subject and talk Missouri, too. I could see they began to have a better opinion of me when they found I was from Missouri (St. Louis), so I ran on Missouri for all there was possible. That was the winning card. The next dash at business we agreed on all points, and concluded the trade. The detail was left to George, who seemed to have the confidence and leadership of the boys. What George did was all right. This was 40 years ago, and I think from that period to the present he has never, to my knowledge, betrayed any confidence reposed. Well, to cut a long story short, we Missouri boys never had a business disagreement. In politics we differed, but we all remained good friends, as long as any were in sight. Quite a number of the nine are now lying beneath the sod, where the balance of us soon will be, simply numbered as a few of the many belonging to the heroic age of California.

ALMARIN B. PAUL.

Oro Blanco, Arizona.

EDITORS PRESS:—In my last communication sent you, I promised to give the readers of your valuable paper a description of other mining properties on what is known as the Yellow Jacket lode, and in which is contained the fast-heooming-famous mine of that name.

This mineral-bearing belt is traceable for five to six miles, upon various locations of which are found large deposits of gold and silver bearing ores of good average grades.

According to reports made by different mining experts, the mineral found on this lode lies deposited between porphyry, gneiss, granite, etc., and wherever development work has been done, the ledge shows a dip of from 12 to 15 degrees northeast, the course of said lode being northwest and southeast, the geological formation and situation being favorable to a true fissure vein.

The Yellow Jacket mine, having a present depth of 250 feet, is now the deepest-worked mine on the lode, and the vein matter may be described as containing talc, slate and quartz carrying about 75 per cent free gold, while the residue, 25 per cent, is combined with sulphur, iron and lead.

The first easterly extension of the above-named mine is known as the Empire, owned by G. S. Phillips and J. H. Forman, and contains a similar deposit to that of the one just mentioned on the surface. Owing to want of capital, this claim has as yet not been developed to a depth exceeding about 15 feet, at which point every indication is favorable to the opening of a good paying property.

The second easterly extension is known as the old Ostrich, a mine worked 15 or 16 years ago. For the working of the ore from this claim there was once erected a ten-stamp mill at Oro Blanco, an old mining town some two and one-half miles distant therefrom. This property has for its present owners Messrs. Handy, Bartlett and Leatherwood, who report very rich ore taken from the mine during the days it was being worked, but the general mill test shows about the average grade of gold ore—about \$12 per ton.

Still east of this and contiguous thereto are found two or three more locations showing good ore along the surface, but none of which have sufficient work done to show up what they may prove to be, veritable bonanzas.

Tracing this lode southeast for a distance of five or six locations of 1500 feet in length each, it becomes invisible along the surface for about two miles, when it again exposes itself to view in huge form, and thoroughly demonstrates the fact that Oro Blanco district is the possessor of the largest mineral deposits in the Territory of Arizona. Capital only is lacking to prove the fact that here consorting through Mother Earth lies buried precious metals in quality and quantity equal to the old Comstock of Nevada.

The first property on the second exposure of the Yellow Jacket lode and the largest mineral showing on the surface, happened to be the property of its lucky owner J. M. Kirkpatrick, one of the oldest residents of Oro Blanco district. This claim is known as the Ragnarook and has had a mill test of over 150 tons of ore, giving no doubt satisfactory results, from the fact that an Eastern party not long ago made an offer for this claim of \$7000 cash, and would in all probability pay double the amount were it purchasable for that price.

Any one visiting this property can see, in large square piles, hundreds of tons more of the same ore, not to speak of the amount in sight not including the above mentioned. Any one desiring further information concerning this claim, can readily obtain it by addressing its owner at Oro Blanco, Pima county, Arizona.

Still easterly and continuous to the above property is found the old Austerlitz, a mine not having been worked for a number of years until within the last two, during which time it has been successfully opened by its present owners, Dr. A. H. Noon & Sons. A mill-test of over 400 tons has yielded sufficient to warrant further labor, and there yet remains enough ore to guarantee a business-meaning company a good profitable property.

Still easterly to the above can be found the Foraken, the Ohina mine, the Pedatlok and others of good repute; and next comes the well-known Montana mine. The Montana has been worked for a number of years past and is being worked to-day with results sufficient to warrant the packing of the ore for 12 miles on burros to the Oon. Arizona mill, where it is successfully treated by Mr. Forman, who, by the way, is one of the best and most competent millmen in these parts.

Adjoining this, last but not least by any means, comes the Border mine, owned by Geoghegan & Forman, who are working it daily with good results.

As I have consumed considerable space in your columns in tracing easterly the different locations of note on the Yellow Jacket lode, I will desist from showing the various workings on each of the claims mentioned until my next, when I shall endeavor to show the amount of work done, together with the feasibility of capital making a profitable investment in this district; and also trace westerly the different properties on the aforesaid lode in connection with work done thereon.

By way of conclusion, allow me to state that should any one with proper means and business intentions desire to know all the particulars about any of the aforesaid properties, he can easily obtain the necessary information

through letter, by applying to any of the parties named.

Middlemen will, however, be entertained only according to their financial and influential weight—personal estimate taken by the party applied to. They are a class of people not very highly appreciated by the residents and property-owners of this district, from the fact that in too many instances have the sales of good claims been foiled by their own general avariciousness, viz.: wanting to make the largest stake themselves and defraud the original finder and owner.

I. C. U.
Oro Blanco, Arizona.

Soapstone.

Its Various Uses in the Trades.

Away back in childhood's days the slate-pencil most desired by juveniles was made from soapstone. The boys liked it because it did not scratch their slates. Few people have any idea of the importance this common rock has assumed in the erection of buildings of the present day.

Mr. W. H. Ramey of Williams & Co., 90 Ann street, N. Y., gave some quite interesting facts in the matter to a representative of the *Saturday Globe*. Soapstone, or steatite, is a mineral of the magnesian family, which has been grouped by Dana under the "Talc Section." It has a grayish-white or greenish-white color. The mineral is found in veins in the earth. It has a dull or fatty luster, and when rubbed on a smooth surface leaves a feeble mark. It is soft and easily cut with a knife. In Europe the substance is found in England, the Shetland islands, in Bavaria and Hungary. In this country the largest quarries are in Vermont, New Hampshire and in Virginia. The mineral is composed mainly of silica and magnesia, with more or less alumina and water.

Soapstone was used by the people up in Vermont soon after the Revolution. Its well-known resistance to the action of both heat and cold was speedily discovered after the first veins were opened by the quarries. To this day there are yet standing many old houses in the Green Mountain State which have grates and fireplaces built of soapstone slabs. Some of the Yankee got up a soapstone pencil, and with it for years the children marked out their simple arithmetic and labored to copy writing lessons. Boston is still the center of the soapstone manufacture. Williams & Co. have their principal office in that city, but their quarries are at Franconstown, New Hampshire. There are many large quarries near Chester, Vermont, owned by the Empire Soapstone Works. In later years the Albemarle Soapstone Co. of this city have opened great veins of steatite in Albemarle county, Virginia. These quarries are located about 100 miles from Richmond. The Virginia mineral is harder than the talc from the Green mountains, while the Franconstown soapstone is capable of a higher polish.

The only limit to the use of the mineral is the scarcity of good steatite. Nine tenths of all that is quarried is found to be of such poor quality as to be only fit for the manufacture of small articles or powders. While easily cut, the mineral is not so easily broken. Soapstone is used in the manufacture of porcelain. It melts easily on glass and is used by glaziers for marking plates of glass before they are cut with the diamond. Tailors use it for marking cloth before they cut it. Shoemakers use soapstone powder to make new shoes slip on easily. Glove-fitters use the powder for the same purpose. It is sold for such purposes under the name of Briancon chalk, French chalk and Venice talc. It is the basis of rouge. It is used for imitating engraved stones, being easily cut and afterward hardened by the action of heat. Then it may be colored by metallic solutions. The figure stone of China is a kind of steatite containing a little potash.

The soapstone of the Eastern States is of a soft talcky nature, very coarse and uneven in texture. The softer parts wear away rapidly and leave the surface rough and uneven. The Albemarle stone is of a close grain. In use it becomes like polished marble and is very strong. The New Hampshire article is capable of a high polish and is used for decorative purposes. The methods of work in the quarries are as yet, as the proprietors guard against competition close by. Many of the quarries are fenced around. The most of the quarrying is done by channeling. Holes are drilled in a square shape about 12x6 feet. Then the big piece is drilled under and lifted from the vein to be worked up in the factories. The latter are near by. The slabs for tube, etc., are made up in the factories, and shipped to desired points where the parts are fitted and placed in position. The parts are joined with bolts and made water-tight with cement.

In many of the new buildings recently erected, soapstone has been used freely in the closets and basins, taking the place of the more showy and expensive marble.

Even in the jewelry trade steatite has been found of value. Crucibles are hollowed out of the mineral. The molds in which are fashioned the delicate crystals for watches are soapstone. In the engine-room powdered steatite has been found useful as an ingredient in steam-packing, and the article is employed as a lubricant.

The use of the article is rapidly extending. A large factory has been established in Chicago recently for the manufacture of stationary wash-tubs, bathtubs and elabe for fireplaces, grates and stoves.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

THE HARDENBURG.—Calaveras *Citizen*, March 14: The Hardenburg mine, on the Amador side of the Mokelumne, promises to become a paying and prominent mine of our State. We were shown last week some fine looking quartz taken from this mine, and also conducted through the lower levels and stopes, so we know where we speak. A test crushing of 100 tons of rock at the Amador mill, which is now being done. They have at present enough rock in sight to keep the mill running a year, and are now running a new level at 400 feet through a vein of fine looking quartz. Although in Amador, the opening of this mine will be a benefit to Calaveras, as it is just over the line and gives work to a number of Calaveras men.

CLINTON CONSOLIDATED.—Amador *Ledger*, March 14: Some very rich ore was taken from the Union mine at Irishtown last week. The rock was sprinkled with free gold. A box of from 50 to 100 pounds of this kind of rock was sent to headquarters in San Francisco. From all that we can learn the property is on a paying basis, with enough rock in sight to last for a year or two. Whether the ledge goes to any great depth is a question yet to be determined. At any rate, all the prospects are encouraging for a solid, permanent mine.

BELL WETHER.—The horse-power whim is in running order, and was started early this week. The shaft is 40 feet deep and has 30 feet of water. It will take several days to drain it. It is expected that this machinery will enable them to sink to the depth of 200 feet.

BELMONT MINE.—This company started their 10-stamp mill last Wednesday, day times, on ore coming from the surface tunnel. Eighty feet yet remains to be driven before an upraise can be started and the mill supplied day and night.

PLYMOUTH.—Cor. Amador *Ledger*, March 14: The people over this way are putting in their time hunting for gold in the gulches where the late rains have washed the dirt away and left it exposed. Some nice specimens have been found. There is no doubt that this part of Amador county would support a much larger population, and that money would be plentiful if it were not for mining land being taken up by agricultural claimants. But so it is, so it seems it will have to remain, as the farmers don't seem to think there is anything good in mining, and will neither indulge in it themselves nor let any one else.

Mariposa.

COULTERVILLE.—Mariposa *Gazette*, March 14: The Iron Duke is showing splendid ore in the tunnel which they are running. The Tyora mine was shut down on Jan. 31, for reasons best known to themselves, but outsiders can guess. The Black Bart mine is still showing favorable prospects as they go down. They are still sinking the main shaft. A rich pocket has just been struck in the Bonadur mine, the extent of which is not yet known, but if it should hold out long and turn out such specimens as were exhibited to us, the company will have all they want in a short time. The Quail mine, on Indian creek, is, and has been running for the last month, to its full capacity on good ore, which is paying better than they expected. They are satisfied that the rock will average at least \$15 per ton. The mine is the property of Mr. Francisco Bruschi of this place, and is a good mine.

CHISPAS.—The mining excitement keeps up, and numerous chispas are picked up in the gulches and streets. A rich spot of ground was found below town where a good deal of gold was panned out by the fair maidens of the forest.

Nevada.

NORTH STAR MINE.—Grass Valley *Union*, March 17: The shaft of the North Star mine is now being sunk for the 2100 level, and a strong vein is showing in the shaft. The upraise from the No. 20 to the 19 level, 700 feet west of the shaft, has just been completed, which opens an extensive block of ground of excellent ore. The mine is looking well and the returns are profitable.

EXTRACTION WORKS.—The new extraction works are practically completed, and the company is about ready to receive concentrates and ores for working. The water-power connection for the works has just been made with the Grass Valley Water Co.'s main pipe line.

THE ST. JOHN MINE.—*Tidings*, March 16: Mining men generally and our business men also are gratified to hear of the encouraging reports from the St. John mine. On Friday last a test was made of some of the quartz from this mine in a hand mortar. Ten pounds of rock gave a prospect of 90 cents, although no free gold was visible in the quartz. The ledge is eight feet wide at a point about 80 feet west of the shaft on the 150-foot level. The quartz carries a large amount of galena and sulphurets. The owners are gratified at the results obtained.

A NEW LOCATION.—Wm. Eddy was showing some quartz on the streets to-day that came from a ledge about six miles northwest of Grass Valley. The ledge is 12 feet wide, the rock showing considerable sulphurets. The piece shown was taken from a shaft 48 feet deep. A crushing of some rock from this ledge several years ago yielded \$4 per ton. The owners of the ledge are Wm. Eddy, John Oliver, Richard Seymour and James Seymour. Water-power can be obtained for working with a fall of 200 feet. The ledge can be worked on the tunnel system at a small cost.

ST. JOHN MINE.—Grass Valley *Union*, March 15: The developments at the St. John continue to be highly encouraging. At a point 80 feet west of the shaft on the 150-foot level the ledge is now showing a width of eight feet, the quartz carrying a large amount of sulphurets and galena, and prospects in free gold. On Friday a test was made of the quartz in a hand mortar, and ten pounds of rock gave a prospect of 90 cents in free gold, although no gold was visible to the eye in the rock. This is very encouraging, and it is not improbable that specimen rock will soon be encountered, as appearances indicate that the drift is getting into a pay shoot. The width of the lode is also a favorable indication, and it is not at all improbable that the St. John is one of

the coming mines in the district. The ledge, at present, stands nearly vertical, and while the supposition is that it will take a snuthly dip, that fact is not likely to be established until deeper working is attained. The general appearance of the quartz taken from the ledge is excellent, as it is lively and has all the points of being gold-bearing.

PEABODY MINE.—Grass Valley *Union*, March 18: The new shaft of the Peabody mine has been started. It is located about 500 feet west of the present working shaft and will be in dimensions 18 feet by 6, divided into three compartments and constructed in the most substantial manner. The surface excavation is now down 12 feet, and the work of putting in the timbers will be commenced immediately. While the shaft is being sunk there will be no interruption of the work in the mine. As the shaft is being sunk from the surface, an upraise will be made to connect with it from the lower levels.

CALIFORNIA.—The Directors of the California M. Co. (the location of the ground being on Deadman's Flat) let a contract on Monday for clearing out and retimbering the shaft. The work is to be started at once, and it is expected that in six weeks the work of opening the drifts and stopping the ore can be commenced.

NORTH BANNER.—The No. 4 level below the adit level in the North Banner mine is now being opened by the cutting out of a new station. The ledge at the bottom of the shaft is large and the ore of high grade. The company will declare another dividend next month.

PITTSBURG.—Work is going on regularly at the Pittsburg mine, there being 15 miners at work on day pay and tribute contract. The mill is run a portion of the time in crushing ore taken from the mine. The ore is of fair milling quality.

Mono.

ANOTHER RICH STRIKE.—Bridgeport *Chronicle-Union*, March 14: We learn that a rich strike has been made in the Goleta shaft in the Jordan district, a body of ore over two feet thick having been cut. It is said the ore is rich in both gold and silver. The Goleta is one of a syndicate of mines owned by a S. F. company, with Dan E. Jones as superintendent. Mr. Jones is also having a fine tunnel run to cut the ledges at a great depth, and to enable the owners to work economically without expensive hoisting works. There is no doubt felt here as to the early coming out of the Jordan district, which only needs capital and well-directed labor to bring the district to the attention of the commercial world.

San Diego.

AT PINACATE.—Riverside *Press and Horticulturist*, March 14: We had the pleasure of a visit Thursday from J. Everett Bird, secretary of the Good Hope Con. Mining Co. This company has been developing the gold mines at Pinacate, five miles east of Parris, for the last year, expending so far about \$30,000 in the work. They paid \$50,000 for the mine in the first place, and having plenty of capital, have gone to work in a systematic manner to develop it. The results are far beyond their expectations, as they now have, at a depth of 400 feet, ore enough in sight to keep a 20-stamp mill at work for five years, on quartz that will run from \$25 to \$2000 per ton. These gentlemen have a perfect bonanza in the Good Hope, as is demonstrated by the fact that a couple of weeks ago they refused \$500,000 for the property. A fine Bryan quartz mill has been set up and just commenced running on the ore this week. Buildings were erected of a substantial character, and every preparation made for the permanent working and developing of this magnificent property. James M. Sigafus is president of the company, and he and Mr. Bird are the men who have brought the property to its present profitable condition. The shipping of gold bullion from the Pinacate mine will soon be a regular thing.

STONEWALL.—Julian *Sentinel*, March 13: W. S. Waterman has our thanks for a very fine specimen taken from the 600-foot level of the Stonewall mine with the diamond drill. It is 18 inches in length and can be seen any day at this office. The management at the mine is feeling pretty good these days, notwithstanding the various rumors floating around in the air.

Sierra.

EXTENSION TUNNEL.—Mountain *Messenger*, March 14: Messrs. Forbes and Kyle made a flying trip to the new extension tunnel (in, March 4th, just one mile from daylight) last Sunday, most of the way on snowshoes. Forty feet was made last week, with the main tunnel through very soft-picking, yellow-colored bedrock that needs no blasting, deemed favorable for closeness to gravel. An upraise was started near the face, last Wednesday, for the channel.

GRAVEL has been found lower down in the Golden Giant. A drift was run off from the incline, 90 feet below where the prospect was bad, and good looking gravel found within a short distance. There is but little doubt but that good pay will be found when the channel is bottomed. A rich ledge has been found in a crosscut of No. 2 tunnel, with a width of five feet, but no hanging-wall, by the Buttes Saddle Co., Sierra City. During the recent rains small pieces of gold have been found in the streets and near the rivers of Downieville.

Shasta.

OLD DIGGINGS.—Cor. Redding *Free Press*, March 12: The miners of Old Diggings pursue the even tenor of their way, upon the hillsides, within the gulches and ravines. They are to be found digging for dear life, as it is of the utmost importance to utilize every drop of water as long as it lasts. The rains which have fallen so far have been barely sufficient to furnish an adequate supply of water for sluicing purposes. Where enough of the fluid cannot be found for the first-named purpose, the rocker is brought into play, though it is the most primitive and slowest method of moving the paying gravel. Still men manage to make a grubstake.

Siskiyou.

BLUE GRAVEL.—Yreka *Journal*, March 11: Lee, Lash & Co., of the blue gravel claim at mouth of Greenhorn, near Yreka, still continue to take out rich pay, and are now working the claim day and night, with a force of 16 hands. The force is divided into two shifts at present, eight men to each shift, with four in the drifts and four on the surface, the latter attending the steam pump, sluices and hoisting machinery. The gold taken out for nine days preceding last Saturday, amounted to \$600, with only day work of four drifters. Instead of

further prospecting at present to ascertain the extent of the pay channel, they deem it best to double the force in performing as much work as possible before the supply of water runs short, as the dry winter this season may not afford much water for as long a run as usual in washing the gravel. When the water gives out, the company will then extend the work of drifting farther along the channel. The extent of the channel is known to reach clear down to the stage-road, a distance of 500 yards, where a prospect shaft was sunk some time ago. With eight men in the drift, not less than from \$125 to \$150 per day will be realized, the gravel paying from \$15 to \$25 per day to each drifter, since first tapping it to the present. Louis Guilbert, who has been sinking a shaft in the Kildore Hills, about three miles south of Yreka, on the east side of Shasta Valley wagon-road, has been obliged to abandon work on account of the late storms filling it with surface water, causing caving in. He will run a tunnel from the creek at the wagon-road, expecting to strike blue gravel within a distance of 250 feet, or may find it all the way to where his shaft was sunk. The creek where he intends starting the tunnel paid very rich in 1884, but blue gravel leads of old channels under hill were not thought of then. W. A. Chamberlin and a number of others have also commenced sinking a shaft in the vicinity of Louis Guilbert's claim, and found sandstone near the surface, under which they believe blue gravel exists. They expect to go down about 150 feet, and will probably have no water to contend with until getting through the sandstone quarry. If successful in finding the blue gravel, they can tap it with a tunnel for good drainage, which can also be utilized for wheeling to sluices, with water from the tunnel for washing. Boyle & Co. and Spencer & Co., of Humboldt, are doing some work in their quartz mines at the head of Humboldt creek, but as the snow is still between three and four feet deep on the mountain, they are unable to get quartz to the mills or to run them to good advantage. The snow is rapidly disappearing, however, under the influence of the late warm rains, and in a few weeks more it will no doubt be all gone, or reduced sufficiently to permit easy hauling and getting over the ground.

Trinity.

HAY FORK QUARTZ.—*Journal*, March 14: A few are still at work on quartz prospects at Hay Fork. Good ore is being taken out, but it has not yet been found in very large quantities. We were told a few days ago that the boys pounded out \$7.50 recently in about two hours with a hand-mortar. The rock goes 50 cents per pound. If they can manage to strike the main ledge it will doubtless be a bonanza.

Yuba.

QUARTZ.—Marysville *Democrat*, March 14: There are many good quartz ledges in this county that have been partially developed in time past, and many others that have not been worked to any extent. Many of our readers who have traveled on the La Porte road will remember a ledge that was prospected by the roadside just beyond Brownsville and on the place formerly kept by Wm. Howell, deceased. Some three years ago, J. C. Campbell commenced to develop the ledge and later put up a small roller mill to grind the rock so as to thoroughly test it, and he kept at work quietly until he became fully satisfied that it was valuable and would pay if worked to advantage. He has now made arrangements to put up a 12-stamp mill this spring and put in all of the latest improvements to save gold, and has no doubt of ultimate success of the mine. Himself and wife, both being practical chemists and assayers, have thoroughly tested the quality of the ore in every way and know what it will do in a working test by mill process.

NEVADA

Washoe District.

CON. CAL. & VA. MINE.—Virginia *Chronicle*, March 14: 1200 level: Continue to extract some milling ore from above the line of the drift run north from the east crosscut No. 1 from the south drift from the shaft station. 1300 level: Have continued to extract some milling ore from the point where the upraise carried up from the end of the east crosscut from the south drift connected with the fourth floor stopes. 1500: The width and quality of the ore which is exposed in the opening 43 feet above the sill floor of this level continues to hold good. 1600: Have continued to take out some ore along and above the line of the drift run east through the old stopes on the sill floor of this level; also from the stopes which are being worked both north and south from that drift. Have continued to stope out ore at the point which is 200 feet south from the north line of the California ground, and 44 feet above the sill floor of this level, and the ore there continues to be of good quality. 1650: The usual quantity of ore has been extracted from the various openings of this level, also some ore in working out from the winze No. 2 at 35 feet above the sill floor of the 1750 level. 1750: Drift running southwest from the northwest drift from the main west drift from the C. & C. shaft has been extended in a south course 14 feet; total length, 579 feet in quartz which yields some milling ore. There has been extracted from all parts of the mine during the week 1540 tons of ore, which was shipped to the Eureka mill. The average assay value of all of the ore worked at that mill during the week (1535 tons) was \$29.20 per ton.

OPHIR.—The east crosscut started from near the end of the drift run north from the drift run west from the winze, 122 feet below the sill floor of the 1300 level, has been extended 25 feet; total length, 35 feet; continuing in a quartz formation, which carries a low assay value.

UNION CON.—East crosscut No. 2 on the 1465 level, started from the north lateral drift at a point 200 feet south from the south boundary line of the mine, has been extended 27 feet; total length, 690 feet; showing strips of clay.

MEXICAN.—The east crosscut, No. 1, started from the main north lateral drift at a point opposite the west crosscut, No. 1, has been extended 24 feet; total length, 540 feet; continuing in porphyry showing clay with a little water.

JUSTICE.—The north drift 822 level was advanced 33 feet since last report and is now out a total distance of 415 feet. The face is in a mixture of clay and porphyry with stringers of quartz.

CROWN POINT.—The west crosscut on the 500 level is out 143 feet. The face is in soft porphyry. Have started to clean out and repair the lateral drift

from the east crosscut from the shaft on the 1000 level, and have completed 110 feet; also engaged in raising from the 1300 stope, and are now above the sixth floor. The top is all clean quartz of low grade.

KENTUCK CON.—Have advanced and timbered the east raise on the 1000 level a total distance of 42 feet. The top is in low-grade quartz. Are cutting out for timbers in the east crosscut from the north drift on this level. Are saving some pay from the bunches of ore encountered.

OVERMAN.—Have extracted 388 tons of ore. Car sample assays average \$19.18 per ton. Shipped to the Brunswick mill 330 tons of ore. On the 1100 level the north drift from the north upraise has been advanced 25 feet through ore of fair grade; total length, 57 feet.

CHALLENGE AND CONFIDENCE.—The joint Confidence and Challenge west crosscut from the north drift on the 1100 level is out 240 feet. The face shows porphyry. The joint Yellow Jacket, Confidence and Challenge north drift on the 1000 level is in 519 feet. The face shows quartz having no value.

BELCHER.—The south drift from No. 3 east crosscut, 2nd level, has been advanced 18 feet; face in a mixture of porphyry and quartz. No. 3 west crosscut, 300 level, has been advanced to 143 feet. The face is in porphyry, clay and low-grade quartz.

CON. IMPERIAL.—Work is still being confined to following up and taking out small streaks of ore on the upper levels and overhauling the old stopes.

SEG. BELCHER.—On the 600 level the east crosscut from the south lateral drift has been advanced 30 feet since last report, and is now out a total of 136 feet; face in a heavy clay.

HALE & NORCROSS.—On the 1100 level the east crosscut on our north boundary has been advanced 20 feet, making its total length 200 feet, and has reached the east clay wall. On the 1400 level the north drift was extended 25 feet; total length, 265 feet. This drift has been connected with the Savage south drift from the bottom of their 1300 winze. The south drift on this level continues in a favorable-looking quartz body, and was advanced 30 feet; total, 106. The face of this drift has reached the south boundary and we will start east and west crosscuts on this line this week. No. 4 west crosscut near our south boundary was advanced 15 feet; total, 60.

SAVAGE.—Milled the past week 440 tons of ore worth \$17.20 a ton as per battery assays. The north upraise, 300 level, is advanced 123 feet and continues in low-grade ore. From the east crosscut on the 900 level are stopping ore of fair quality. From the face of the north drift on the 800 level we have started east crosscut No. 1 and advanced the same 35 feet. This crosscut shows seven feet of fair-grade ore.

CHOLLAR.—Winze 80 feet south of north line, 750 level, is down 102 feet. The bottom is in clay. The 1100 level incline station is completed and are now sinking for chutes. Extracted and sent to the mill 544 tons of ore worth \$16.92, as per battery assays.

POTOSI.—On the 930 level the east crosscut from the winze is out 200 feet; face in clay and porphyry. The winze is down 124 feet on the incline below the 1300 level and has about 40 feet farther to go on the slope to reach the 1400 level. The bottom is in clay and porphyry with streaks of quartz. East crosscut from winze, 1300 level, is out from footwall 18 feet; face in porphyry with streaks of quartz yielding assays from \$7 to \$10 a ton.

UTAH.—On the 725 level the northwest lateral drift from the shaft has been extended 47 feet, total length, 573 feet, passing through vein porphyry showing clay and very little water.

GOULD & CURRY.—800 level: Have extracted from old stopes during the week 56 cars of ore of fair quality.

BEST & BELCHER.—800 level: All work on this level has been suspended. 1100 level: Started an east crosscut from top of raise from 1200 level; extended same 12 feet; face in hard porphyry. West crosscut No. 1, 100 feet above 1200 level, has been extended 10 feet; total, 172 feet. Face in quartz and porphyry.

ANDES.—On the 420 level have been repairing a portion of main north drift. The north drift on this level was extended seven feet; formation quartz, clay and porphyry. Work has been resumed in face of east crosscut from south drift on 425 level.

Columbus District.

HOLMES.—Chloride *Belt*, March 14: Captain Nelson Westcott has been appointed assistant superintendent for the Holmes M. Co. and for the Candelaria Water Works & M. Co.; also for all the properties belonging to and controlled by the Duris Syndicate in Nevada, and he has full power to act as superintendent in the absence of the superintendent, D. H. Jackson. Ten stamps were dropped in the Holmes mill yesterday morning, and ten more will be let down about Tuesday next. During the six days in which the mill was shut down it has been thoroughly overhauled and needed repairs made. Two new roasting furnaces have been rebuilt from the ground up. The one in operation works very satisfactorily.

Taylor District.

MONITOR.—White Pine *News*, March 14: The rumor comes from Taylor to the effect that after the ore now extracted is worked the Monitor mine will be closed down indefinitely and all work will be concentrated in the future on the Eberhardt-Monitor Co.'s property at Eberhardt. But two weeks ago all reports agreed that the Monitor mine had at no time looked better in several years. If the above rumor is founded on fact it is like unto a flash of lightning out of a clear sky.

Tuscarora District.

NEVADA QUEEN.—Times-Review, March 13: North drift on the 650-foot level has been advanced 21 feet in the vein; water has increased.

NAVAJO.—Stopes above the 350-foot level have been improved considerably and are now in good ore.

BELLE ISLE.—The 350 stopes continue to produce a high grade of ore; 12 cars of rich ore and 19 cars of concentrating ore were broken. West crosscut, 450-foot level extended 14 feet. Spar seams are beginning to show in the face, which is getting quite wet. South drift from same has been extended nine feet and suspended.

NORTH BELLE ISLE.—North drift from Belle Isle 450 level extended 16 feet; the vein continues large with bunches of good ore. The 500 stopes continue to look well, and ruby ore is beginning to show in

the south end. No. 4 upraise from the 600 level has been extended 13 feet and will connect with the 500 level in a few days.

COMMONWEALTH.—East crosscut on the fourth level has been advanced 12 feet into the vein. Progress has been slow on account of having to catch up the footwall side of the vein where the water started it to cave; face is in vein showing clay with mineral mixed through, giving low assays. Water continues to come as strong as at any time. West crosscut advanced 33 feet and timbered; face is in vein formation with heavy clay seams, slight seep of water.

NORTH COMMONWEALTH.—Second level—North drift from west crosscut extended 25 feet in the vein, assays from same \$120 per ton. Hoisted during the week 13 cars first-class ore assaying \$248 per ton, and 32 cars second-class, average assay \$26.90 per ton.

Jersey District.

BLOSSOM.—*Central Nevada*, March 14: S. W. Surgeon, who departed yesterday from Jersey mining district, took with him a large supply of provisions for the Blossom Mining Co. Four partners of them are taking ore from their mine in the district, which shows \$50 in silver and \$8 in gold. Average assays as high as \$123 silver and \$26 gold have been recorded. The Jersey district and the old townsite are 50 miles south of this point and 25 miles west of Bridges station. Hereafter the ores will be hauled by team and shipped from Battle Mountain.

Lovelocks District.

ANTIMONY MINE SOLO.—*Silver State*, March 13: The Theis-Hutchins antimony mine at Lovelocks changed hands yesterday, and the deed was placed upon record in the County Recorder's office. They received \$8000 in cash and is to receive \$2000 more in a short time. They claim this antimony ore will sell in the London market for \$115 to \$125 per ton.

ARIZONA.

MOHAVE COUNTY MINES.—*Miner*, March 14: Now is the golden hour for prospectors to hunt for the precious metals in Mohave county. The recent rains have washed a great deal of soil down from the hills, exposing in many places pieces of float rock and ledges heretofore buried in their depths. This county at this season of the year is a land of promise to the hardy seeker after the wealth of the earth. In the Black range, running for miles parallel with the Colorado river, can be found ledges rich in silver and gold. In the Cerbat range of mountains the mineral-bearing belt is seven or eight miles wide and about 80 miles in length; and in the Wallapai, Music and Peacock mountains are buried treasures more vast than ever dreamed of by mortal man awaiting the day when the horny-handed sons of toil shall liberate them from their earthly tomb. Nearly every metal known to science exists in some form in our mines, so that from the prospector after "black-som" to the one after bright, sparkling gold, each and every one can have his choice. The water has at last been overcome in the Cupel mine and sinking commenced. Darden, Shippey and Sherick have a carload of ore ready for shipment on the dump of the Empire at Chloride. The Empire mill in Todd Basin is running on ore from the Suffolk mine, and seems to be turning out considerable bullion. The Denver M. & M. Co. have had between 80 and 90 tons of Mexican ore worked in the Empire mill, Todd Basin, which gave satisfactory returns. There is a strong possibility that work will soon be resumed on the Montezuma mine in the Black Canyon range. The Homestake mine in Mineral Park, it is said, is proving itself a good property, as the ore is getting richer than ever. The ore now being taken from the bottom of the shaft averages between \$300 and \$400 per ton. Beebe's team took the new Ingersoll drill for Barry & Baldwin out to the Sunlight mine, last Saturday. Del. Beebe made a flying trip to the Diamond Joe mine the first of the week. He informs us that there are now about 150 tons of ore on the dump of the mine awaiting shipment to the sampler. This lot of ore will average over 100 ounces to the ton.

OLIVE CAMP.—*Cor. Tucson Citizen*, March 14: Work at the Sierrita mine, under the superintendence of Mr. Rhodes, has been suspended. The work ceased Sunday morning, and the cause is only matter for conjecture. The men were paid off, and do not, so the *Citizen's* informant states, know whether the shut-down is permanent or otherwise, though they think it is not unlikely that it is for the time only, when new machinery—concentrating—will be put in. There is plenty of good ore in all the levels. The ore has been shipped as fast as mined, and in the main shaft has reached a depth of 235 feet. The Olive mine has been leased to Messrs. Frank Shey, Chas. Avery and — Fogerty, and they are taking out fine ore—silver and lead—much of it better than 250 ounces to the ton. At the Matchless, owned by Messrs. Taylor, Scott, Hughes and Baxter, shipments are being made regularly. The ore runs over 200 ounces. Two men are hired there. A shipment was made last week from the Wedge mine. This is a good property and development work on it will be pushed constantly. The old whim at the Sierrita has been purchased and is being put in. Five men are employed there. Three Italians are taking out some fine ore on the west end of the Wedge, at a mine they have lately opened there. They have gone just through the blue and will ship soon. O. J. Doyle, the Olive postmaster, is working three men on the Annie. He made a carload shipment of graded ore about three weeks ago. Some of the ore went \$395 to the ton. The Richmond has lately been leased to a Tucson party named Carruthers who went out there this morning. He leased it of Mr. Royce. L. F. Fries has a nice little mine at Olive with four feet of ore. It runs from 150 to 250 ounces, and his occasional shipments furnish a good income. Much chloriding is being done throughout the Olive country.

BRITISH COLUMBIA.

KOOTENAY LAKE COUNTRY.—*Cor. Nelson Miner*, March 14: I believe that Toad mountain will turn out to be like Leadville's Carbonate hill; that ore will be found in almost every shaft sunk. I have been on the mountain off and on since 1888, and have been all over the Silver King and Kootenay Bonanza ground. You can hardly stick a pick in anywhere on part of the ground without uncovering ore. If machinery was on the Silver King mine,

fully 250 men could be working to advantage, even though the present depth is but 150 feet. As it is, 50 men could now be employed at stopping ore alone. Fifty men in the Silver King could extract 100 tons a day. The ore body is exposed for a distance of 100 feet; in one place it is shown to be 45 feet wide and neither wall struck; the shaft shows this body or deposit to be 35 feet deep with solid ore in the bottom of the sump. Estimating that it is only 100 feet long, 45 feet wide, and 35 feet deep, would give 157,500 cubic feet of ore, which at 13 feet to the ton is 12,115 tons. The lowest value placed on the ore would give over a million dollars in sight in this one place alone. There is also a large quantity of lower grade ore near the surface.

COLORADO.

AROUND GEORGETOWN.—*Courier*, March 14: Very little can be said in a mining way this week except that the shipments of ore have not been as brisk as they might had the weather been more propitious. The mountain trails are in a poor condition from the almost incessant fall of snow of the past two weeks. And yet one can see the trains of those much-abused and invaluable little burros wending their way up the almost impassable mountain-sides daily, regardless of the inclemency of the weather, to the mines that cannot be reached by wagon-road, and returning heavily laden with ore. The shipments from the station will be a great deal less than last month, not that the mines have produced less, but on account of the very disagreeable weather prevailing. Up in the Argentine districts, better named the Arctic, the snow is so deep that the miners of that Siberian clime are hibernated. The mines in and around Georgetown and Silver Plume are so situated that they are come-at-able during all seasons of the year, hence almost every available foot of ground has been located.

MINERAL FARM.—*Aspen Times*, March 14: The prospects for the Mineral Farm are more and more encouraging. The recent discovery of boulders of rich ore has been followed by the development of some mineral in what appears to be a permanent streak, which becomes more important as the incline goes down. The work progresses without any hitch, and we may look for some interesting news from that quarter in a short time. The improvement is so well maintained that the management is encouraged to believe that an ore chute is being approached. A strike in that property would be of the greatest value to the camp, as it would carry the paying district northward nearly a mile.

SILVER BRICK.—There is a report on the street to the effect that a strike of good ore has been made in the Silver Brick at the foot of Smuggler mountain. This claim lies just east of the Smuggler. Nothing is known of the character of the discovery, but the report of the find is coupled with another that \$60,000 has been offered for the property.

AROUND SILVERTON.—*Standard*, March 14: On the Syracuse Pride, two feet of mineral has been struck in the lower level just under the big ore body above. The force has commenced stopping and finds that both the grade of mineral is much better and the streak much larger. The crosscut on the Pride of the West is being pushed ahead at an average rate of five to six feet a day. The power drills are working to perfection. Some days two headings are put in and in hard rock only one; each heading squares up four and a half feet. The contract for sinking the shaft of the Silver Ledge is about completed. Gottlieb Wagner, who is contracting on the south drift, is in 60 feet and Peter Bataleno is in 40 feet in the north drift; each has a contract for 100 feet. They have ore in both drifts and the mine is looking well. Theising Bros. have just completed a 60-foot crosscut on the Custer Extension, on Galena mountain, on the south side of Cunningham gulch. After cutting the lead, which shows 18 inches of solid mineral—galena, copper, gold and silver—they commenced sinking a shaft and are down 10 feet, with mineral improving. They will sink 50 feet, and in the spring run another tunnel 100 feet below the present one and raise to make connections with the shaft.

DAKOTA.

HILL CITY.—*Deadwood Pioneer*, March 13: With the Harney Peak Co. capitalized at \$15,000,000, with over 1000 mining claims surrounding it in every direction, it is no wonder that Hill City is putting on metropolitan airs and keeping pace in improvements with many older towns in the Hills. The vast sums of money the Harney Peak Tin M. Co. has disbursed in the purchase and development of their mines has built up the city, and the new mill of 250 tons daily capacity that will be erected the coming spring will settle the tin problem and make Hill City the tin metropolis. While there are none of the company's mines down to a depth of 300 feet, they are sinking steadily on the Cowboy, Addie, G. W. Coates and the Nevada No. 2. These claims are provided with steam hoists, pumping and compressed-air machinery of capacity for working to a depth of over 500 feet. Numerous tunnels, the longest of which is 950 feet in length, are being run, and the dumps show an abundance of ore. The finest of this comes from the Cowboy and Addie. The largest tin crystals ever discovered in the world are from the former mine. Hill City is growing substantially.

IDAHO.

PROSPECT.—*Elmore Bulletin*, March 14: Dave Barclay has a good prospect adjoining the Keystone claim on the Red Warrior side of the ridge south of town, which he calls the Little Daisy. He has recently shown us some specimens of very rich gold ore from this claim, and though the vein where exposed is small, it certainly justifies thorough development. Mr. Barclay will soon commence extracting ore from the Little Daisy, and will doubtless make several millruns during the coming summer.

PINE GROVE.—Superintendent Towne is actively engaged in preparations to resume work on the Pine Grove Co.'s mines. The stamps of the Elmore mill have been making music and grinding out gold the past week.

FROM SMOKEY.—*Cor. Ketchum Keystone*, March 14: As to mining matters of the camp, work has been prosecuted with the same energy and force as

was started in with last fall, with results more or less favorable. The King of the West is looking remarkably well, though only working a small crew of men. Mr. Dell Shearer has struck a good streak of ore on his Sunday lease. The Silver Star continues to take out a quantity of high-grade ore, besides its milling ores. About the old town of Smoky proper, the two leases are still under headway. Messrs. Oliver, Jones & Turner have taken out a small quantity of ore during the winter, and continue to strike pockets as they go on. They have had much water and ice to contend with. Messrs. Covert & Reid are still prospecting their strike of last January, and when they commence stopping it is fair to presume that they will take out a good-sized bunch of high-grade ore.

MONTANA.

THE EUREKA.—*Phillipsburg Mail*, March 12: The Eureka G. and S. M. Co., whose property is situated near Georgetown, is prepared to begin work just as soon as spring opens and the road to the property becomes passable. The necessary machinery for doing the development was taken in last fall, and they intend making extensive development this year. This company is made up almost exclusively of Phillipsburg gentlemen and capital.

DRUMLUMMON OUTPUT.—The output of the Drumlummon for the month of February was as follows: Fifty-stamp mill, 338 tons, valued at \$65,300; 60-stamp mill, 2600 tons, valued at \$23,300; total, \$88,600; running expenses, \$53,200; profits, \$35,400.

BI-METALLIC EXTENSION.—The excessive flow of water in the Bi-Metallic Extension shaft caused some delay in the work early this week, but larger pipes have been put in and work is again under way.

GRANITE MOUNTAIN OUTPUT.—The output of the Granite Mountain Co. for the past week is 39 bars containing 58,500 ounces silver and 240.4 gold.

BLUE BIRD.—*Butte Miner*, March 12: The litigation which caused a total suspension of operations at the Blue Bird mine for nearly a year and deprived many laborers of employment, besides paralyzing for a time the earning power of a vast amount of invested capital, has just been settled out of court, and upon terms which permit the immediate resumption of work at the mine and mill owned by the big English company. This announcement will cause great satisfaction to the laboring miners as well as to the business men of the city, and the effect of the resumption of operations at the Blue Bird mine will be beneficial to the entire community. The 325 men who were thrown out of work by the shutting down of the mine and mill will once more draw pay, which means that over \$30,000 is to be added monthly to the amount now paid out for labor by the mining companies of the camp. The settlement was effected yesterday, when the Blue Bird Co. purchased of James A. Murray all his right, title and interest in the claims immediately adjoining and surrounding the Blue Bird. Mr. Murray received \$10,000 in cash and accepted the company's notes for \$50,000 more for his interests, and an agreement that both parties should withdraw their suits was signed.

THE ANACONDA.—*Butte Inter-Mountain*, March 14: This mine must always head the list when the great red metal producers are under discussion. The shaft is now down just 1000 feet with stations cut at every 100. Drifting and stopping are being pushed on nearly all the levels. The levels above have been considerably worked and much of the ore has been taken out, though there yet remains enough in sight to last for years. There are employed in the mine about 420 men above and below. The most ore at present is being taken from between the 600 and 900 foot levels. On the 1000 of this property the ore body is about 20 posts in width, or about 100 feet, but the ore contains more iron than that nearer the surface. The ground at the 1000-foot level has been completely prospected, and at every point the indications are bright for a great and continuous future. On the surface the company has machinery that is capable of sinking to a greater depth when required, but that will be many years hence. The most of the drilling is done by Burleighs, more especially in the stopes and drifts, but in some places hand-drilling is resorted to where it is impossible to get in the pipes. The timbers used in the stopes are 10x10, and those in the stations are 12x14. These timbers are pulled into position in the stopes by a little engine that is taken about the mine on trucks and which is run by compressed air. This mine now fills up all its old stopes with waste that is procured from the country rock adjoining and from a distance. Should these places come together now it would work no injury to this large property. In some places where it is impossible to get a sufficient amount of waste, the old stopes are bulkheaded up with heavy timbers. The company puts in the timber only where it is impossible to procure the waste, as the latter is the only safe way of securing the ground in this camp. It is almost impossible to picture the immense quantity of timbers used in this way.

NEW MEXICO.

GOLO.—*Silver City Enterprise*, March 13: The cleanup from ten stamps on Pacific extension ore, the property of Bell & Stephens, three weeks run full time, amounts to just 150 pounds of gold. Who says that stamp milling will not pay when conducted properly, judiciously, economically and skillfully in Pinos Altos?

SILVER-LEAD.—Great activity is now going on, particularly in silver-lead properties below the Pass. The Cooke Bros. and Bob Williams, Tom Fox and others have at present showing the biggest lead ledges. Experts from El Paso are in camp every week trying to secure the lead output. The lead ores average about 30 per cent and carry 20 ounces and upward in silver.

COPPER.—Capt. P. J. Mitchell, M. E., in charge of the development work on the Johnny Bull mine at Stein's Pass, reports that during the month of February while cutting out stations, putting in stulls and finishing timbering work on the 70-foot level, a body of copper ore was exposed and stopes cut out for over 50 feet in black and red oxides and carbonates. The vein is 18 feet wide as far as opened out, and as yet shows no signs of any hanging-wall. In addition to this body of ore there is also a 15-foot

body of carbonates showing some red oxides at the depth of 100 feet in the shaft on the hanging-wall side of the line formation and as yet shows neither signs of hanging nor foot wall.

LONE MOUNTAIN.—Brockman and Beall yesterday shipped another carload of high-grade ore from the Good Luck. They have also located and are developing another claim to the north of the Good Luck, which is a promising prospect for the amount of development work done on it. There has been a great deal of excitement in mining circles during the week, about the strike made last Saturday by Wm. Brahm and Doc Belt. An *Enterprise* representative visited the mine and found the ore body fully as large as represented, being fully 20 feet in width. The ore is an iron and lead carbonate containing silver as a chloride; first-class samples showing over 300 ounces per ton. If the mass of ore will average one-half or even one-fourth of this, the gentlemen will be well entitled to their recently acquired titles of "Bonanza Bill" and "Silver Dollar Doc."

OREGON.

PLACER MINING OUTLOOK.—*Bedrock Democrat*, March 12: Mr. A. Reiney, a prominent placer miner of Humboldt basin, was yesterday met by our reporter and in response to a question propounded as to the placer-mining outlook in that section the gentleman replied: "Last year was the best placer season that we have had for the past five years. More ground was worked and with better results than usual, all on account of a good supply of that ever indispensable article—water. The deep snows in the mountains furnished a good supply of water and fed the streams until late in the season, and that is the reason why the season was so long and profitable. At present we have about three feet of snow in the basin, and now, getting at your question, I will say that the coming season promises to eclipse that of last year. Every one who owns a piece of placer ground in our section will be up and doing when the season opens, and as we have every assurance of a good water supply and a long season, you can depend on the output of the shining metal being greater than for any season for the past eight years. Among the placer miners who are preparing for the spring run I might name the following: Colt Bros., owners of valuable placer diggings near Canyon creek, are preparing for a long run. Littig & McCarty will work their ground on Gordon Bar. Lum Sing & Co. will work the Rogers & Copland places, north of City Gulch, for all they are worth. Andrew Jensen is preparing to commence operations on valuable placer grounds, situated on Glenn Glory. Blair, Glover & Seigel will make the dirt fly on their Amelia placers and they expect a long and profitable season."

UTAH.

MINING AT FISH SPRING.—*Salt Lake Tribune*, March 12: James Chipman and W. H. Grant of American Fork have gone into mining quite vigorously at Fish Spring. They have two feet of ore and have taken out so much of it as to start shipping. A number of teams were started out the other day to bring this ore to market, and it is expected to keep teams on the road steadily. They have had many assays made and the lowest went over 100 ounces silver and 25 to 40 per cent lead. Near their mine is another in which James Preslin of American Fork has purchased an interest, and it runs still better in the quality of the ore. Assays made show all the way from 96 to 700 ounces silver and 25 to 56 per cent lead, the lead being the highest where silver is the lowest.

THE BUFFALO BILL.—J. J. Cushing and Fred Gillette have a small force of men developing the Buffalo Bill mine, this side of Tintic, a short distance from the Salt Lake & Western Railway. They have a tunnel driven on the six-foot vein of low-grade ore, and it is developing so well that they will incorporate a company in a few days to prosecute work more vigorously on it.

AMERICAN FORK.—S. Osborn, who is interested in several mining properties in American Fork canyon, writes from Chicago that he has secured money for their development and associated good men with him in the enterprise, and that about April 1st he will be here to push work. He says his work this season will boom American Fork district and make it a large producer of ores. T. B. Many of Cleveland, Ohio, who has a lease and bond on the Sunday mine, American Fork canyon, writes that he will soon be here to work the property, and will drive development with much vigor this spring and summer. The Treasure Con. Co. has had three men doing deadwork on their property in American Fork canyon all winter. Their property adjoins the well-known Miller mine. They have ore ready to ship.

THE NEW EAGLE DISTRICT.—The Midland Investment Co. is in receipt of a letter from its foreman, whom they sent, with several other men, to the Deep Creek country some time ago, and who located five claims in the new district of Eagle. The foreman writes that in sinking on these five claims, the vein gets better and the ore richer as they go down, but have not reached deeper than 12 feet on any of them. They have located several other claims the past month.

THE OLD MASSACHUSETTS.—*Park Record*, March 14: A recent transaction that gives great encouragement to a large number of Park City residents, who long have had faith in the ultimate richness of the Massachusetts mine, is the fact that Messrs. M. R. Evans, Wm. M. Curtis and A. A. Smith have closed negotiations with the principal stockholders of the Massachusetts M. Co. to obtain the control of that property, which was done at the meeting of the directors of the company held in Salt Lake on Saturday. Mr. M. R. Evans of Salt Lake City has secured the control of two-thirds of the stock, and it is his intention to develop the property as soon as roads and weather will permit. The shaft, which is now down about 600 feet, will be sunk to a distance of 1000 feet, when drifting for the vein will be started. All the machinery necessary for that purpose is on the ground, and but little delay will be occasioned. Mr. Wm. M. Curtis, late superintendent of the Anchor, and who had charge of the Massachusetts when last operated, will be placed in charge of the work. The revival of the Massachusetts, with such a strong backing of thorough miners, will undoubtedly redound to the credit of all concerned.

MECHANICAL PROGRESS

The Mannesmann Process Fore-shadowed.

That there is nothing new under the sun is proved by every-day experience, and if the Mannesmann tube process has not been anticipated, it has at least been foreshadowed. This is the experience of F. J. R. Carulla, formerly manager of the Landore Siemens Steel Works, who points out in a contemporary that Messrs. Dyson and Hall invented what they called a reeling machine, which was worked at Sheffield. To quote Mr. Carulla:

"Just over 20 years ago—viz., on Oct. 31, 1870—a patent was granted to George Walter Dyson and Henry Arthur Hall for 'improvements in rolling and finishing circular metal plain or irregular rods and tubes,' which as regards rods has had a considerable local application in Sheffield, especially at the Carbrook Forge, where the invention was first brought out. As regards tubes, it may be said, without in the slightest degree detracting from the ingenuity and originality of Messrs. Mannesmann, that the germ of their already famous process is evident in this invention. As the Mannesmann process, at no distant date, is likely to revolutionize the tube industry, any analogies that may assist in understanding its mysterious operation will not fail to be of interest, but apart from this, the machine of Dyson and Hall, which, as already hinted, has been mainly applied to the cold-rolling of 'rods' or round steel bars, is so little known that no doubt it will be thought worthy of description for its own sake.

"The name 'reeling' has been given to the operation performed by this machine to distinguish it from that done by parallel rolls where the bar is simply passed backward and forward without having any rotary movement imparted to it. The rod to be operated upon is, in the reeling machine, passed between conical-shaped rollers—truncated cones projecting from the faces of discs fixed at the ends of shafts or axes, the combined arrangement being called a 'reel.' . . . This action gives a spiral motion to the bar under operation that makes it travel between the coned faces of the reels, fresh portions being brought under action in a similar manner to that of the Mannesmann mill. The resemblance of ideas in the two cases is also obvious when the means for holding the piece to be operated on are compared. . . . Dyson and Hall specify 'the rod or bar is prevented canting during the rolling by snitable guides, or it may be made to pass through the mouths of tubes arranged at the ends for the purpose, or between rollers which may be feed rollers or not.' The reels can be moved end on toward one another, and the discs approached or separated to suit different diameters by means of hand wheels and screws.

"The bars subjected to this operation come out straight and perfectly circular in section, no turning being necessary where a plain bar all of one diameter is required. Not the least important effect, however, is the toughening produced on the material of the bar by the spiral compression, the tensile strength being increased over 20 per cent in the case of mild steel. The spiral fiber is the very essence of the remarkable strength of the tubes made by the new process now in operation at Landore. Dyson and Hall specify that 'there is no limit to the dimensions of the discs, as those can be suited to the size of the articles to be produced or finished, and discs of different sizes can be used as pairs, and these may travel at the same or different speeds.'

"We can imagine that some conception of the possibilities of their process as recently developed had crossed the minds of our inventors, when we read: 'We have referred more particularly to rods or bars, but tubes can be acted upon in the same manner, whether for rolling or finishing them as before spoken of.' But no doubt the difficulties of obtaining sufficient power, which have been successfully overcome by Messrs. Mannesmann, stood in the way of progress in the direction indicated.

"The writer well remembers one occasion during his connection with the Carbrook Forge when a breakdown occurred, which was sufficient to render every one cautious of further experiment with the appliances then at command. One other distinctive feature of the reeling machine which also assimilated it to the Mannesmann mill is—as Mr. Gordon states for the latter—that much greater accuracy is required in the adjustment of the rolls than is dreamed of in the philosophy of iron and steel millwrights. The parts in the machine, as in that described by Mr. Gordon, are as accurately fitted as those in a locomotive or marine engine. The reader will not fail to perceive the numerous points of resemblance between the two processes. At the same time, let it be understood that it is in no spirit of detraction that these lines are written, but simply as a contribution having a wide interest in connection with an ingenious process that is likely to become an important adjunct to our industrial resources."—*London Iron*.

PROTECTION AND BESSEMER STEEL.—That our protective system has done something substantial for our iron production has been shown. The record as to Bessemer steel makes equally instructive and significant reading. In 1878 the United States produced a little over 800,000

net tons of Bessemer steel, with Great Britain slightly in the lead. In 1889 Great Britain turned out, in round numbers, 2,400,000 tons, having increased 200 per cent. During the same year our total production was 3,800,000 tons, a net increase of 375 per cent. The figures for 1890 are not yet obtainable, but will no doubt increase our lead. The production in Great Britain was only limited by the demand, for her manufacturing resources are almost boundless. But for our protective system, she would have supplied us, thus more than doubling her output. When we consider what a vast amount of labor is required to produce 3,800,000 tons of steel, who can have the effrontery to say that as a nation and a people we have not been immensely, almost incalculably, benefited by our system of protection to American industries? The McKinley bill may have made some unfortunate changes, but the fundamental principle of protection is founded in reason and demonstrates itself.—*Chicago Jour. of Com.*

The Age of Steel.

Steel has been selling at Pittsburg at a less price than iron. This bit of news, which comes to us upon good authority, justifies the statement that the much-talked-of "age of steel" has at last arrived. The statement, which to many would seem to involve an absurdity, is reasonable enough to the initiated. One of the greatest expenses of manufacturing iron consists in the large amount of labor required, a considerable portion of which is of a highly skilled character, commanding in consequence good wages. Skilled labor is also required in making steel, but the number of men of all grades required to operate a plant of given capacity is small in comparison to running an iron-mill with same output in tons.

For some purposes, the manufacture of electrical machinery and appliances for instance, iron can never be supplanted by steel, but for most uses the latter is far superior and can be made to generally take the place of the former. But iron is not destined to yield the crown without a struggle. Recent inventions have cheapened the production of bar iron and a still further reduction in cost seems highly probable. Much iron of good quality is now made direct from the ore, or rather about 50 per cent of ore is used in connection with an equal quantity of pig. A mass of ore is suspended above an ordinary open hearth in which is a bath of iron made from the pig metal. The heat wasted in the ordinary process serves to heat the ore to a dull red color. This drives off most of the deleterious matter, after which it is allowed to descend into the bath, producing very good iron.

This and other devices may somewhat retard the triumph of steel, but none the less certainly it seems destined to come, and that in the near future. Cheap steel will work wonders for this country and enable us in due time to compete with the manufacturers of the world, and that on an equal footing.—*Chicago Jour. of Com.*

Wire Rope.

A wire-rope manufacturing company gives the following hints:

There are two kinds of wire rope manufactured. Ropes with 19 wires to the strand are more pliable and are generally used as hoisting ropes. Those with twelve or seven wires to the strand are stiffer and best adapted for guys, ferries, rigging and transmission purposes. Wire ropes are made of six strands, laid about a center of hemp or wire, the former being more pliable, and wearing better over small pulleys and drums.

Wire rope is as pliable as new hemp rope of the same strength. The greater the diameter of sheaves, pulleys, and drums, the longer the rope will last.

For safe working load, allow one-fifth to one-seventh of ultimate strength, according to speed and vibration. Speed increases the wear.

Wire rope must not be coiled or uncoiled like hemp rope. When not on a reel, roll upon the ground like a wheel to prevent kinking.

To preserve wire rope, cover it thoroughly with raw linseed oil, mixed with vegetable tar. This mixture forms a protecting surface and preserves it from undue wear.

To preserve wire rope under water or underground, add one barrel of fresh-slacked lime to a barrel of mineral or vegetable tar, hoil well, and saturate the rope with the mixture hot.

Galvanized wire rope should never be used for running rope. One day's use will wear off the coating of zinc, and the rope will soon rust.

Too much care cannot be taken with the pulleys, sheaves and drums over which ropes are run. The grooves should be lined with well-seasoned blocks of hard wood set on end, rubber, leather, or some soft metal. Thus the life of the rope will be greatly lengthened, and greater adhesion secured than when the rope is operated over smooth and hard surfaces.

Iron ropes, operated under proper conditions, will give perfect satisfaction when the work to be done is not too heavy. Steel ropes should be substituted for iron when lightness is required, or when a greater strength becomes necessary. The object in substituting steel for iron is to decrease the wear rather than reduce the size of the rope.—*The Engineer*.

A CONVENIENT DEVICE.—Near Bordeaux, France, there is a buoy in the harbor which is connected with the mainland by telephone. Ships arriving can thus communicate with their owners.

SCIENTIFIC PROGRESS.

UTILIZING WASTE FURNACE PRODUCTS.—At three or four of the Scotch iron works, the Furnace Gases Company are paying a yearly rental for the right of collecting the smoke and gases from the blast furnaces. These are passed through several miles of wrought-iron tubing, gradually diminishing in size from 6 feet to about 18 inches, and as the gases cool there is deposited a considerable yield of oil. At Messrs. Dixon's, in Glasgow, which is the smallest of these installations, they pump and collect about 60,000,000 feet of furnace gas per day, and recover, on an average, 25,000 gallons of furnace oils per week; using the residual gases, consisting chiefly of carbon monoxide, as fuel for distilling and other purposes, while a considerable yield of anhydrous ammonia is also obtained. In the same way a small percentage of the coke ovens are fitted with condensing gear, and produce a considerable yield of oil, for which, however, there is but a very limited market; the chief use being for the Luogen light and other lamps of the same description, and also for pickling timber for railway sleepers, etc. The result is that four years ago the oil could be obtained in any quantity at 3d. per gallon, though it has since been as high as 2s. 6d. It is now about 2d. per gallon, and shows a falling tendency. Make a market for this product, and the supply will be practically unlimited, as every blast furnace and coke oven in the kingdom will put up a plant for the recovery of the oil. As, with the limited plant now at work, it would be perfectly easy to obtain 4,000,000 or 5,000,000 gallons per annum, an extension of the recovery process would mean a supply sufficiently large to meet all demands.—*The Engineer*.

CHEMICAL ANALYSIS IN METALLURGY.—As is well known, chemical analysis demands the greatest precision, and therefore every addition to the supply of information on the subject is to be welcomed. A work has just issued from a forge addressed to those engaged in metallurgy, written by Baron Hansjupner de Jousorff, which has been translated into French. In reviewing it, a Parisian contemporary says: This practical treatise of metallurgical chemistry will be appreciated not only by those who are occupied in that particular branch of analysis which relates to ores and metallurgical products, but also to those who are interested in the apparatus and metallurgical processes, in refractory products, in blending beds, in different heatings, in ovens and furnaces, and in the analyses of gases. The translator shows how useful a chemist may be in such works. Some years since, he says, a laboratory was only kept up from vanity, as an object of luxury showing the scientific culture of the manager. The war forced our engineers to push as far as possible the study of steels, and that study cannot be fruitless without very delicate chemical analyses. They made themselves *au courant* with the laborers of Lowthian Bell and Bessemer and with the methods of analysis which had contributed so largely to the success of the Kruppa. To-day we are on a level with the Germans and the English, if, occasionally, even we do not succeed in surpassing them at least on some points.

FROZEN 6000 FEET DEEP.—For many years scientists have been perplexed over the phenomena of a certain well at Yakutsk, Siberia. As long ago as 1828 a Russian merchant began to sink this noted well, and, after working on it for three years, gave it up as a bad job, having at that time sunk it to a depth of 30 feet without getting through the frozen ground. He communicated these facts to the Russian Academy of Science, which sent men to take charge of the digging operations at the wonderful well. These scientific gentlemen toiled away at their work for several years, but abandoned it when a depth of 882 feet had been reached, with the earth still frozen as hard as a rock. In 1843 the academy had the temperature of the soil at the sides of the well taken at various depths. From the data thus obtained they came to the startling conclusion that the ground was frozen to a depth exceeding 6000 feet. Although it is known to meteorologists that the lowest known temperature is in that region of Siberia, it is conceded that not even that rigorous climate could force frost to such a great depth below the surface. After figuring on the subject for over a quarter of a century, geologists have at last come to the conclusion that the great frozen valley of the Lena river was deposited, frozen just as it is found to-day, during the great grinding-up era of the glacial epoch.

SNOW WORMS.—We alluded in our last issue to the appearance of what were called "snow worms" in Randolph county, West Virginia. The great of the snow was covered with them. The *Scientific American* wrote to Prof. Riley, the agricultural entomologist at Washington, for an explanation of the phenomena, who replied as follows: "You send two distinct larvae. The small species, of which there were 8 to 10 specimens, is the common Pennsylvania soldier-beetle (*Chauliognathus Pennsylvanicus*), a carnivorous species which in the larva state destroys plant lice, bark lice and the eggs and young larva of a number of injurious insects. This insect hibernates in the larva state and has occasionally been observed, both in Europe and in this country, fairly awaking upon the surface of snow, having been driven

from its hibernating quarters by some peculiar weather combination. It hibernates at the roots of grasses, under stones and logs, and under the loose bark of stumps, logs, and old trees. The other and larger larva, of which there was only one specimen in the box, seems to be a variety of the bronzy cutworm (*Nephelodes violans*), an insect which also hibernates in the larva state, and has also been observed occurring in large numbers on snow."

COLD WATER WITHOUT ICE.—The following method of obtaining a constant supply of cool water at all times is described by the *Railroad and Engineering Journal* as being in general use in Hanover, York county, Pa. The water from the wells is unfit to drink on account of bad drainage, so water has to be brought a long distance in pipes, which is very warm. To cool it, a plan has been adopted which is quite ingenious. A galvanized tank is placed beneath the water in the wells, which is very cool. This tank is connected with the water mains and the domestic delivery pipes, and the method gives an abundant supply of cool water during the whole summer, and can be adopted in all cities, towns or in the country. If a well is available, it can be used; if not, by simply digging a hole in the ground deep enough so as not to be affected by the surface temperature, and burying the tank, it will answer equally well. This hole might be dug in a cellar or outside the building. If the water has any impurities in suspension, such as mud, the tank should be made accessible, so that it can be cleaned separately.

HOW THE WORLD APPEARS TO THE LOWER ANIMALS.—In addition to the organs of hearing, touch and smell, Sir John Lubbock has found upon the antennae of insects certain organs that seem to be connected with senses that we know nothing about. Experiments made upon certain fresh-water crustaceans show that they are sensible to sounds corresponding to more than 40,000 vibrations per second (sounds that we cannot hear), and to ultraviolet rays that we cannot perceive. Now all the rays that we can perceive appear to us with definite colors, and it is almost the same with these animals; so it is probable that they see colors unknown to us, and which are as different from those that we are familiar with as red is different from yellow or green from violet. It would result from this that natural light, which seems white to us, would appear colored to them, and that the aspect of nature would be entirely different to them from what it is to us. It is possible, therefore, that to certain animals, nature is full of sounds, colors, and sensations that we have no idea of.

ELECTRICAL STORMS.—An electrical storm of unusual violence visited South Dakota about the first of February. During the storm, the large amount of electricity was noticeable everywhere. Persons coming in contact with each other or with any metallic substance would throw off visible flashes of electricity with a sharp, snapping sound. When this occurred to persons a very perceptible shock was experienced, even through thick clothing. Commenting upon this phenomenon, the *Scientific American* correctly says: "The phenomena described were those of a winter electric storm. These storms are not frequent, but they are well understood by meteorologists. They are also called magnetic storms, because the magnetic needle is strongly affected during such electric manifestations. Their origin is supposed to be coincident with the development of aurora, and probably caused by disturbances in the sun that produce sun-spots. Their coincidence has often been the subject of astronomical observation and record."

EFFECTS OF HEAT AND PRESSURE ON ROCKS. M. Daubree has continued his researches on the effects produced upon rocks in contact with gases suddenly developed by means of such explosives as gun-cotton and dynamite. Temperatures of 2500° and pressures of 1100 atmospheres, thus obtained, have been sufficient to fuse and pulverize the rocks experimented upon in a very marked manner. The results lead M. Daubree to believe that the perforated pipes or *diatremes*, diamantiferous, volcanic, or otherwise, and much of the subaerial dust and oceanic deposits are formed by such actions as he has obtained in the laboratory. He also shows that rocks may acquire an apparent plasticity under the influence of pressure.

IN GREENLAND, north of 75° of latitude, the entire land is covered with a sheet of ice estimated to be about 5000 feet thick over all the valley regions. So far as has been observed, no mountains are discernible above the ice, or even any elevations which can be attributable to underlying mountains. The whole is a vast plain at an elevation of from 5000 to 6000 feet above the sea level. This is probably the last remnant of the great ice cap which must, at some time in the past, have covered nearly or quite all the land from the pole to the equator.

ARTIFICIAL RUBIES.—Some time ago mention was made in these columns that two French gentlemen, M.M. Fremy and Verneuil, had succeeded in producing rubies artificially, but the crystals were exceedingly minute. After long-continued study and experiment it is now announced that they have succeeded in continuing the process over several months, and producing as much as seven pounds of rubies at a single operation.

GOOD HEALTH.

Failure of a Noted Case of Skin-Grafting.

Some two or three months since Mr. John O. Dickerson, a prominent Mason of Chicago, had a cancer removed from his person by the knife. The wound refused to heal, and 132 of his brother Masons came heroically to his relief. Each allowed a piece of skin to be removed from his person, to be transplanted upon the body of the afflicted brother. The victim of cancer and the surgeon's knife died February 24th.

It is truly melancholy to know of the immense suffering and loss of life by this fearful cancer malady all over the country and the world. Over 2000 people are dying of this dread disease in the United States every month, and yet we have in this city a most undoubted cure for it, to which we have been calling the attention of our physicians and the people generally for some four years past, with very little response from either the physicians or the press, although great numbers of the people are becoming interested in the matter.

We have given masses of testimony of every character from patients that have been cured and from individual physicians who have watched the successful treatment of patients with more or less carelessness; but the faulty as a body have thus far refused to investigate or make any official report either for or against.

We are pleased, however, to state that several of the more considerate are beginning to give the cure some attention, and are watching the convalescence of several very pronounced cases now under treatment, and it is to be hoped that the result in those cases will lead to an official investigation by our City Board of Health or some other official body.

We have no interest in the matter, so far as the practitioner is concerned. The end which we desire to reach is such an official medical investigation as will place the value of the ascertained remedies beyond all controversy. If such investigation should prove favorable, there are those who stand ready to do whatever may be required to place the remedies in the hands of physicians everywhere. We hold that the evidence is amply sufficient to warrant the Board of Supervisors in asking the City Board of Health to look into this matter officially.

THE TREATMENT OF DANDRUFF.—Dr. Edward Clarke, in the *Lancet*, states that he has had good results in persistent dandruff from the following treatment: The scalp should first be thoroughly washed with soap and hot water and then thoroughly dried with a warm and soft cloth; there should then be rubbed into the scalp a glycerole of tannin, of the strength of 10 to 30 grains to the ounce. Very obstinate cases will require the higher strength of tannin. This process should be repeated twice a week at first, once a week afterward. If tannin fails, as it will in some cases, then resorcin is had to resorcin. After the formation of dandruff has ceased, the head should be rubbed daily with olive oil containing, to the ounce, ten grains of carbolic acid and a dram of oil of cinnamon.

THE MICROBE OF RHEUMATISM.—A distinguished French physician, after much research, thinks he has discovered a micro-organism, specific in character, which is the direct cause of rheumatism. He reports that he has isolated and cultivated the microbe, injected it into the carotid artery of rabbits, and engendered an inflammation which to all indications is the same which accompanies inflammatory rheumatism in human beings. These investigations will undoubtedly stimulate parallel researches by other investigators and may lead to important therapeutical results.

POISON IN WALL PAPER.—We have already called attention to the fact that there is danger of poison from wall paper, especially that which contains green colors, which are generally produced by arsenic. We see by an Eastern exchange that ex-Mayor Cobb of Boston is now suffering from what is pronounced an incurable illness attributed to the absorption of arsenical poison from wall paper in his own house.

PEPSIN IN PINEAPPLE.—It is stated that there is an element in the common pineapple similar to pepsin, and of such remarkable strength that the juice of a single apple will digest ten pounds of beef. It is further stated that the juice of the fruit is a very active solvent of the membrane found in diphtheria.

A DIPHTHERIA LYMPH.—The Government medical authorities at Washington have, after many experiments, announced the discovery of a lymph which gives immunity from diphtheria, and they hope to make it a certain cure for that disease.

HAIR DYES should always be avoided. All the various "hair restoratives" are both unwholesome and uncleanly. The loss of color of the hair depends upon constitutional causes, and it is rarely or never restored.

DIED OF TOO RAPID GROWTH.—A 15-year-old boy has just died in Brooklyn, N. Y., of too rapid growth. At the time of his death he was six feet two inches tall, but did not weigh 100 pounds.

USEFUL INFORMATION.

ELECTRIC MINE SIGNALING.—Whoever has been in a mine is familiar with the laborious method employed in giving signals to the men at the top of the shaft. It is a task that requires considerable muscle and endurance for the man at the 12th level to seize the lever and ring 12 bells, to indicate that the cage is wanted at that level. He will probably consume half a minute in giving the signal, and by the time this has been repeated at the surface to the engineer, it is a minute to a minute and a half before the engineer knows what is expected of him. This will all be changed at the Liding-tou. The mine will soon be supplied with electric signals, when a man at any level will only have to go to the shaft and throw a switch, and the small dynamo which will be used for that purpose will do the rest; for it will be a small dynamo and not batteries that will supply the current to operate these signals. Besides the saving in labor and time, it will obviate the possibility of mistakes, because a switch thrown at a certain level will unfailingly give the signal for that level, and the box containing the signaling apparatus being under lock and key, cannot be tampered with by those not in authority.—*English Paper.*

SUBSTITUTE FOR GUTTA-PERCHA.—A Portuguese gentleman, Senor da Costa, says *Invention*, is reported to have discovered an excellent and abundant substitute for gutta-percha, near Goa. It is the solidified fluid which issues from the Nivolo-antem, which grows wild in the Concan district, which is generally planted for hedges. It is insoluble in water, softens under heat, and hardens in the cold. It receives, moreover, and retains a given mold, can be cast into very thin sheets, and is capable of taking the minutest impressions upon its surface. Though white when it flows from the tree, in its dried state it is of a chocolate color, closely resembling gutta-percha. If this be true, the discovery is of enormous value.

LEATHER RAILWAY BRAKES.—A company has been formed in New South Wales for the purpose of exploiting the manufacture of railway brake shoes from compressed leather. Waste leather scraps are steeped in a solution and subjected to a hydraulic pressure to mold them to any desired shape. The leather shoe is said to possess distinct advantages over that of iron, with superior efficiency in every way. The leather shoe weighs 4½ pounds, against 21½ pounds for iron, and it will wear three times as long. More than this, it has a greater coefficient of friction, so that 40 pounds air pressure is as effective as 70 pounds with iron brake shoes.

QUESTIONABLE INVENTIONS.—It is said that Maine has produced a Keely with a mysterious motor. He lives in Monroe, and says that his machine is capable of one to ten horse-power, and does not derive it from steam, water, gas, or any agency now known. He is going to hitch the machine to churns and pumps. It is also said that Mr. Maxim, the inventor of the "Maxim gun," claims to have constructed an engine of 500-horse power, weighing only 1100 pounds, or 2.2 pounds per horse-power. Some of the large and most efficient engines have about 112 pounds dead weight per horse-power, including water.

ERASING LINES ON TRACING CLOTH.—If you wish to alter tracings, scrape out the lines with a sharp knife and rub smooth with a Faber Ink-eraser; then get a bottle of negative varnish, dilute it with alcohol so as to be quite thin; give the erased place a light coat of this varnish. When dry, you cannot detect the difference, either in the way the spot takes ink or in the way it prints. Another thing, the spot does not catch dirt as it does when not coated. The varnish may be bought of any dealer in photo supplies.

SPONTANEOUS COMBUSTION OF A TREE.—One of the sacred "tallow trees," standing at the entrance of the grounds which surround the imperial mansion of his majesty, the Emperor of China, spontaneously fired in some of its upper branches and burned to the ground on Dec. 15th. Scientists say that the tallow tree often fires of its own accord, but the superstitious Chinese take it to be an evil omen, and are greatly excited.

STEEL COLOR ON BRASS.—A steel color is developed on brass by using a boiling solution of arsenic chloride. A concentrated solution of sodium sulphate causes a blue coloration. Black, as on optical instruments, is obtained from a solution of platinum chloride, to which tin nitrate has been added. In Japan, brass is bronzed by using a boiling solution of copper sulphate, alum and verdigris.

WOOD CLOTH.—Cloth is now made of wood. Strips of fine-grained timber are crushed between rollers, the filaments carded in the usual manner with textile into parallel lines and spun into thread, from which the cloth is woven.

THE BLAST FURNACE.—It is estimated that the energies manifested by the action of a blast furnace over the limited space to which it is confined, are fully equal in proportion to that of the most active volcano.

A CONDOR was recently shot in Scott's valley, Santa Cruz county.

STEAM BOILER NOTES.

Red-Hot Furnace Experiments.

Some years ago much was said and written upon one of the clauses in the instructions given by Mr. L. E. Fletcher to firemen, with reference to shortness of water, where, in case of shortness of water being discovered, he advises the turning on of the feedwater. This is, no doubt, a very startling method of procedure to those who have not gone very fully into the matter, and at the time its advisability was very much questioned. To set the matter at rest, the Manchester Steam-Users' Association had a boiler constructed, in order to put the matter to a practical test under working conditions, and the chief engineer's report is now before us. Being a somewhat elaborate production, we are scarcely prepared to pronounce decidedly upon its purport, beyond stating that the experiments themselves were conducted under conditions closely approximating to those of every-day work.

The furnaces were hared of water by opening the blow-off cock and allowing the water to escape, while good, bright fires were burning, which could not fail to overheat the plates. When sufficiently heated to melt discs of lead, tin and zinc, the feed was suddenly turned on through special pipes, which injected the water directly on to the heated plates, but in no case, as is often assumed, was this followed by a sudden generation of steam at an excessive pressure, but in one case actually a reduction of pressure took place. Certainly there was one mishap, but this was clearly proved to be due to not turning on the feed soon enough. Some exceedingly practical information is given on several other subjects, especially as regards the bogging upward of the flue tubes, which was accurately ascertained by means of rods, and found to be as much as one-half inch in some cases.

There are also particulars of tests in which different types of boilers were put to work and the different temperatures taken above and below the furnaces were pointing out clearly the inadvisability of hurrying fire when raising steam. We think more details might have been given, and the work would have been acceptable at a much earlier date. However, we consider that steam-users are greatly indebted to Mr. Fletcher for the valuable information now given.—*The Mechanical World, London.*

MIXTURE OF STEAM AND HOT GASES.—A new method of working motor engines, with hot gases and steam, is the subject of recent English patents. According to the invention, the mixture of the steam with the hot gases to form a charge for doing duty in the working cylinder of the engine is effected in a chamber in the following way: First, the chamber having supplied a charge of mixture to the working cylinder and been thereafter open to an exhaust, hot gases are passed through to clean and dry it. Then, while the chamber is yet full of hot dry gases, it is closed. Then steam at a suitable pressure is admitted, mixing with the hot gases therein and forming the working mixture for use in the cylinder. This mixture, being at a high pressure, then expands in the cylinder, which, after the former has done duty in effecting a stroke of the piston, is opened to the exhaust and the spent mixture allowed to escape from it. For a single-acting engine, one mixing chamber suffices. A double-acting engine, however, requires at least two, in each of which the process takes place; but the chamber or chambers to supply actuating fluid to one end of the cylinder (or of each cylinder) must be separate from those that supply the other end, in order to allow ample time for the process of cleaning out, drying, filling with hot gases and admitting steam thereto to take place in an efficient manner, in each chamber, in the required order.

THE STEAM JACKET.—Prof. Thurston has recently made a compilation extending over 40 pages of figures and opinions as to the value of the steam jacket. He believes a discussion of the data thus collected will do much to reconcile the conflicting opinions as to the value of this device, which go to show that according to the circumstances the use of a jacket may be highly advantageous or actually deleterious. A summary of the results obtained by the various authorities shows that the gain by use of a jacket ranges from zero to over 30 per cent.

INCREASED USE OF COMPOUND LOCOMOTIVES.—According to a statement of Herr von Borries, Royal Inspector of Railroad Construction in Hanover, Germany, the number of compound locomotives in process of erection, and in use, increased, in the year from Nov. 1, 1889, to Nov. 1, 1890, from 580 to 1034, divided nearly as follows: Germany, 430; England, including those built for South America, India, etc., 523; Italy, 2; Russia, 32; Switzerland, 11; North America, 8; street locomotives, 28; total, 1034.

THE SAFETY-VALVE.—Be sure that your safety-valve is in working order; start it from the seat every day. Have a string attached to the end of the lever run through pulleys to a convenient place, so it will be handy to pull, and have climbing on top of the boiler occasionally. Take the valve apart and clean it. See that it works easily and does not bind.

SHOP NOTES.

The Man Not the Shop.

Many mechanics are striving to get forehanded enough to establish their own shops, hoping that in time they will grow into larger works, where they can execute heavy contracts. This is a laudable ambition, but it happens sometimes that men go into these enterprises with the expectation that the shop will grow of itself and that the public will seek them merely because they have shops. It should be borne in mind that nothing is to be had in this world without labor and pains, and that if a shop becomes known and has an established reputation, it is because some one is interested in pushing it. By whatever means it is secured, publicity must be had, for it is indisputable that people cannot give work to shops they do not know of. This point is one that escapes the attention of the average craftsman in any line, but particularly of engineers and machinists.

If men want new or old work to do in their shops, they must go where such work is to be had. Too many, however, wait for the work to come to them, and wait in vain usually, because some one in the same line, with more enterprise, has got ahead of them. It is queer, but it is true, that some mechanics will not hunt up work, because they cannot get rid of the feeling that they are asking favors of strangers. This is absurd. There are no favors in trade. If a man gets a contract it is because his terms are favorable to the buyer, and for no other reason. No manufacturer gives contracts for "love and affection," as wills are sometimes made.

It is not the small beginning which is in doubt, but the small beginner. Is he the man to succeed? This is the question. Has he the faith which will remove mountains, the courage, the courtesy, the business tact which will command success? If he has, it makes no difference how small the shop is on the start. A small shop with a large man in it will succeed, where a large shop with a small man in it will fail.—*Plumbers' Journal.*

CLEANLY AND ORDERLY WORKSHOPS.—There is no doubt about it, cleanliness about a shop is one of the rules which should be most rigidly enforced. There is no excuse for permitting piles of rubbish, scraps, etc., to lie around on the floor and benches, neither should the machinery be allowed to remain covered with grease and dirt. Clean machinery tends toward the keeping of everything in the best order. Dirt and grease often hide indications which if observed in time might prevent a breakdown and an attendant loss of property, and possibly a loss of life or an injury to the workmen. Workmen should take pride in keeping their benches and surroundings as free from litter as possible. It is an unpleasant sight to go into a shop and observe a workman, who desires some particular small tool, rummaging over the numerous scraps, tools, etc., which cover the machine or bench at which he is working, in order to find the tool he desires to use. Each workman should have a particular place for each tool, and return it to its proper place as soon as he is done with it. It is a very simple matter to clean up a bench at least once a day.

THE MAIN BUSINESS IN ALL SHOPS is shaping iron and steel—that is, getting it into shape so it will fit together, and also removing the surplus that does no good. The operations carried on may be divided into two classes—hot and cold treatment. You easily separate these in your mind. Hot processes are molding or casting when the metal is fluid and runs into shapes by gravity, and also include what I call plastic treatment, that of pressing, hammering, bending, and so on. This is forging. It comes under my department. Now these hot processes are not exact ones, because the material is hot and in an expanded condition, and allowance must be made for shrinking, as well as a surplus to cover finished dimensions. Cold processes are exact, because the material is treated at its normal temperature and remains as it is left. These processes consist mainly in trimming away the allowance the smith and the molder must make for shrinkage. This includes turning, planing, filing, drilling, scraping, and so on, and can be done by rule, in a degree, and can be done without much mental skill, if there are machines and manual skill.—*Industry.*

THE CARE OF MACHINERY.—Proper care of machinery is of vital importance in the economic running of a mill. While the quality of machinery varies greatly, operators differ still more in their management and care of machines. One operator will take a new machine and run it for five or six years without causing any perceptible depreciation in its value. Another man will take a similar machine and in two or three years he leaves it a total wreck. The machine being equal, the wreckage must lie in the operator. Every operator should perfectly understand the make-up of his machine and how to properly adjust all its parts. Running a machine does not consist simply in knowing how to run a hoard through it; yet the knowledge possessed by many operators does not extend much further than this. Learn your machine thoroughly, study it, acquaint yourself with the principles upon which it is constructed, and know how to adjust every part of it, not by rule, but by an intelligent understanding of the why and wherefore.

TABLE OF CONTENTS.

EDITORIALS.—The Woodbury Ore Concentrator; The Vulcan Wire Ropeway, 177. Passing Events; No More Gold Bars for Shipment; The New Land Law; Hydraulic Mining, 184.

ILLUSTRATIONS.—The Woodbury Ore Concentrator; The Vulcan Wire Ropeway, 177-185.

MISCELLANEOUS.—The New Land Law, 178. Soapstone, 179.

CORRESPONDENCE.—Old Time Reminiscences—Senator Hearst; Old Blanche, Arizona, 179. MECHANICAL PROGRESS.—The Mannesmann Process Foresawdower; Protection and Bessemer Steel; The Age of Steel; Wire Rope; A Convenient Device, 182.

SCIENTIFIC PROGRESS.—Utilizing Waste Furnace Products; Chemical Analysis in Metallurgy; Frozen 6000 Feet Deep; Snow Worms; Cold Water Without Ice; How the World Appears to the Lower Animals; Electrical Storms; Effects of Heat and Pressure on Rocks; Artificial Rubies; Miscellaneous, 132.

GOOD HEALTH.—Failure of a Noted Case of Skin-Grating; The Treatment of Dandruff; The Microbe of Rheumatism; Poison in Wall Paper; Pepsin in Pineapple; A Diphtheria Lymph; Hair Dyes; Died of Too Rapid Growth, 183.

USEFUL INFORMATION.—Electric Mine Signaling; Substitute for Gutta-Percha; Leather Railway Brakes; Questionable Inventions; Braising Lines on Tracing Cloth; Spontaneous Combustion of a Tree; Steel Color on Brass; Wood Cloth; The Blast Furnace; Miscellaneous, 183.

STEAM BOILER NOTES.—Red-Hot Furnace Experiments; Mixture of Steam and Hot Gases; The Steam Jacket; Increased Use of Compound Locomotives; The Safety Valve, 183.

SHOP NOTES.—The Man Not the Shop; Cleanly and Orderly Workshops; The Main Business in All Shops; The Care of Machinery, 183.

MINING SUMMARY.—From the various counties of California, Nevada, Arizona, Colorado, Idaho, Montana, New Mexico, Oregon, Utah, Wyoming, 180-181.

MINING STOCK MARKET.—Sales at the San Francisco Stock Board; Notices of Meetings, Assessments, Dividends, etc., 188.

MARKET REPORTS.—Local Markets, Eastern Metal Markets, etc., 188.

Passing Events.

The joint resolution previously adopted by the Senate has been adopted in the Assembly, requesting Congress to authorize the appointment of engineers to investigate the mines of this State, and to have the power to devise and execute plans by which mining in all its branches may be carried on without injury to agricultural lands or rivers of the State. Congress is asked to appropriate \$1,000,000 to this end.

The will of the late Senator Hearst leaves all his mines and mining property to his widow. Mrs. Hearst thus becomes the largest mine-owner of any lady in the United States.

Charles N. Felton has been elected U. S. Senator to fill the unexpired term of the late Senator Hearst.

The new land law, published elsewhere in the PRESS, merits the close attention of all interested in the public lands. The measure is one which makes radical changes in the previously existing system.

The City Council of Butte, Montana, some time since passed an ordinance declaring the smoke fumes from the roasting ore heaps and smelters proper a nuisance and a decided menace to public health, yet in that ordinance it was distinctly stated that the smelting companies were to have nine months in which to adopt contrivances for either destroying or carrying off the fumes. So far only three months of this time has elapsed, but the Health officer has issued warrants for the arrest of offenders.

No More Gold Bars for Shipment.

On Tuesday of this week the superintendent of the U. S. Assay office in New York received notice from the director of the Mint that \$1,000,000 in gold bars ordered by two firms would not be allowed to be taken for export. This is the first time in eight years that the Government has refused to allow gold bars to be taken out for export.

The privilege of converting gold coin into bars has hitherto been accorded without hesitation, but it was found that speculators took advantage of the same to await a rise in foreign exchange and thus be prepared to make money out of the advance. The Treasury officials have long felt that the exercise of the privilege tended to take gold out of the country, and for this reason, as well as to prevent unnecessary speculation in the commodity, the application, in accordance with a decision reached some days ago, was refused.

The refusal was based upon the new law enacted a few days before the close of the last session of Congress, whereby the Secretary of the Treasury is authorized to convert gold coin into gold bars upon application, charging therefor at the rate of four cents for each \$100, or he is authorized, in his discretion, to refuse outright to convert the coin into bars. This refusal does not prevent the melting of the coin into bars by private parties, but they cannot do it as cheaply as the Government, the average cost outside of the Government mints being 12 cents for \$100.

Exporters of gold prefer to send it in bars, if possible, for the reason that the loss from abrasion and other causes is greater in the case of gold than in gold bars. It is therefore believed that the new departure will tend to check the exportations of gold from the country.

Acting Secretary of the Treasury Nettleton, referring to the refusal to allow gold bars to be exported, said the action was taken with the full approval of the President, under authority of the recent Act of Congress giving the Secretary of the Treasury discretionary power to refuse such exchanges when deemed necessary for the interests of the Government. On the last exchange a charge of four cents per \$100 was imposed, but as this rate does not seem to deter the shipment of Government gold, the Treasury Department decided to discontinue the exchange altogether for the present.

The New Land Law.

Elsewhere in this number of the PRESS we give the full text of the new land law passed by the late Congress, and which makes very marked changes in our public land system. The new Act is the most sweeping that has ever been passed since the enactment of the original homestead law. The timber-culture and pre-emption laws are repealed, with provisions for the protection of vested rights. The desert-land law is amended to compel the expenditure of at least \$3 per acre in irrigation works and the amount that can be taken up is limited to 320 acres. The homestead law is subjected to important modifications. All lands, with immaterial exceptions, are withdrawn from public sale. Provision is made for the acquisition of title to lands in Alaska for manufacturing and commercial purposes and for townsites. The President is given authority to withdraw timber land from entry at any time and to any extent. Irrigation is encouraged by the provision with relation to reservoir sites.

The only reference to mineral lands in the new law is the section which states "that townsite entries may be made by incorporated towns and cities on the mineral lands of the United States, but no title shall be acquired by any such towns or cities to any vein of gold, silver, cinnabar, copper or lead, or to any valid mining claim or possession held under existing law. When mineral veins are possessed within the limits of an incorporated town or city, and such possession is recognized by local authority or by the laws of the United States, the title of town lots shall be subject to such recognized possession and the necessary use thereof, and when entry has been made or patent issued for such townsites to such incorporated town or city, the possessor of such mineral vein may enter and receive patent for such mineral vein and the surface ground appertaining thereto. *Provided*, that no entry shall be

made by such mineral-vein claimant for surface ground where the owner or occupier of the surface ground shall have had possession of the same before the inception of the title of the mineral-vein applicant."

Hydraulic Mining.

We have in a previous number of the PRESS given the Voorhies joint resolution on the mining industry which was adopted by the Senate some weeks since and has finally been adopted by the Assembly. It will without doubt be signed by the Governor, as it contains among other things his remarks on the subject of hydraulic mining given in his inaugural address. In truth, it was due to the fact that the Governor's inaugural address brought this subject up forcibly that the joint resolution was introduced and adopted. He urged the Legislature to take the initiative in obtaining the assistance of the Federal Government.

The main resolutions in the document are as follows:

Resolved, By the Senate of California, the Assembly concurring, that we earnestly but most respectfully request Congress to pass a law authorizing the Secretary of War to appoint a competent Board of Engineers, to consist of three or five members, as may be deemed best, whose duty it shall be to investigate the mines or mining districts of this State; said Commission to have the further power of devising and executing plans whereby mining, in all its branches, may be carried on without injury to agricultural lands and the navigable streams of the State. And to the accomplishment of this end we ask Congress to appropriate one million dollars, believing, as we do, that the Government will be repaid many fold for such action.

Resolved, That a copy of this preamble and resolution be forwarded to our Senators and Representatives in Congress by the Governor, under the seal of the State.

Coming officially from the Legislature of the State of California, this request will be more apt to succeed than if as a mere petition. Congress must pay some attention to the matter under the circumstances, and take steps to grant the relief asked for. Thousands of people have been made poor by the closing of the mines, and the Government should take active measures to find out some possible way by which the property of these men can be restored to usefulness without detriment to others.

NATURAL GAS IN ENGLAND.—Quite a little excitement was recently created in the neighborhood of south Durham, Salt district, England, by the discovery of natural gas. On the 7th of February, while parties were engaged in sinking a drill-hole for salt, there was a sudden outburst of water and gas, thrown high into the air. The gas was soon in a blaze from a small fire near the well-hole, and burned with great fury for some 24 hours, when it gradually ceased. It is thought that a permanent supply of gas might be obtained by sinking a little deeper. At the time of the outburst they were down about 900 feet. At last accounts there was some dispute about the nature of the gas, some insisting that it was not the true [natural gas] as was found in such abundance in this country. Should it eventually prove to be the same, a great fortune is predicted for the future of that locality, as well as the north of England generally.

ROBERT M. FRYER will be remembered as a man who got the whole mining community excited about the "Fryer process" some years ago, and who built works at Grass Valley, which were a failure. He is now about to have built an ocean steamer, 206 feet long and only 16 feet wide at the point of greatest beam, with which he hopes to attain a speed of 35 miles an hour without any special effort. To keep this knife-blade from capsizing, she will carry a keel weighing 68,000 pounds. This is simply applying the principle of the English type of sailing yacht to a steam vessel. The new steamer is to be built at Baltimore.

MEXICAN ORE IMPORTS.—The Nogales Herald prints a statement of the amount of ore sent through the Nogales custom house during the month of February, which shows a heavy increase over any previous month in the history of the town. These are the figures: Silver ore, 1,441,225 pounds, valued at \$123,601; lead ore, 165,528 pounds, valued at \$5491; copper ore, 21,066 pounds, valued at \$1056. The bullion importations were: Gold, \$33,600; silver, \$124,758. The amount of duties collected on the ore was \$2555.84.

Mining Bureau Museum.

Following are among the recent contributions to the museum of the California State Mining Bureau:

Garnet—Almandite in mica schist, with khaetzite, Santa Margarita Ranch, San Diego; from H. W. Fairbanks.

Mica, Department Baja, Vera Paz, Guatemala; David B. Rea.

Manganese ore—Pyrolusite, Corral Hollow, Alameda Co.; Ad. Sommers.

Silver ore with chrysocolla and crystallized gypsum, Candelaria, Esmeralda Co., Nev.; J. L. Callison.

Calcite—massive, East Oakland, Alameda Co.; R. C. Look.

Chrysolite, Richmond Co., Quebec, Canada; Benj. E. Lyster.

Michigan currency, value \$3, issued in 1838 and popularly called "Red Dog" or "Wild Cat" money; A. S. Penfield.

Pearls from fresh-water mussels, Sugar Creek, Wisconsin; Mrs. J. H. Martin.

Siderite (carbonate of iron), with hematite on quartz, Antwerp, N. Y.; Williamsburg Scientific Society.

Indian flint arrow head, Blannerhasset Island, West Virginia; Jas. Goucher.

Hauzerite (sulphide of manganese). Very large and fine crystals, Ragusa, Sicily.

Lignite, 25 miles northeasterly from Redding, Shasta Co., vein 21 feet thick; Oscar C. Schulze.

Quartz (Saccharine), 12 miles north of Willits, Mendocino Co.; E. R. Shimmie.

Sandstone, crushing strength 8000 lbs. to the square inch, Ventura Co., Ventura Brownstone Co.

Gold quartz with chalcophyllite, 60 miles above Juneau, on the coast of Alaska; G. W. Yount.

Borax (borate of sodium), Saline Valley, Inyo Co.; A. Neuschwander.

Bernardinite (a hydrocarbon), San Bernardino Co.; Geo. D. Craig.

Cyanite (silicate of aluminum), in mica schist, near Los Angeles; C. N. Pring.

Cobalt ore, erythrite and smaltite on calcite, San Gabriel canyon, Los Angeles Co.; W. H. Adams Jr.

Beryl and columbite, Portland, Conn.; E. F. Sheldon.

Granite, anorthite, New Glasgow, Quebec, Canada; H. Sampard; also specimens of trap, calcite, syenite, dolomite, feldspar and trachyte, contributed by the same.

Calcite in layers interstratified with chlorite, Ravenna, Los Angeles Co.; J. Robertson.

Chrysolite (silicate, etc.),—Knight's Ferry, Stanislaus Co.; W. A. Threlfall.

Gypsum (black color, due to oxide of iron).—Ventura Co.; A. J. Maus.

Spinel.—Bergen Hill, N. J.; Miss S. P. Monks, who contributes also numerous other mineral specimens from various localities.

Opal.—Variety opal agate, La Silletta, Jalisco, Mexico; Williamsburg Scientific Society.

Pyrite.—Iridescent on calcite, Wooden mine, Egremont, Cumberland, Eng. Marcasite (sulph. iron), Dover Cliffs, Eng.; Williamsburg Scientific Society.

Erythrite (hydrous arsenate of cobalt).—Cobalt bloom, San Gabriel canyon, Los Angeles Co.; W. H. Adams.

Silver.—Native in smaltite, arsenide of cobalt and nickel; W. H. Adams.

Silver Ore.—Silverado mine, Napa Co.; Dan Patton.

Elk Horn.—H. Davis, Oakland.

Graphite on Quartz.—Santa Rosa, Sonoma Co.; J. M. Walker.

Fossil tooth, Centennial claim, Klamath river, Siskiyou Co.; numerous fossils of various kinds, consisting of the jaws, teeth, tusks and other bones of mammoths and other gigantic animals, together with Indian relics, specimens of ore, etc., found on San Miguel, San Nicolas and Santa Rosa islands, off the coast of Southern California; Japanese arrow-heads of the kind formerly used in warfare; A. Hattori.

Old style Chinese matchlock, with ammunition and accoutrements, captured from the Chinese by the French in 1882—a curious implement; Geo. A. Montell.

U. S. half dollar of 1836; C. W. Ormsby, Oakland.

Sapphire (corundum), 4 specimens, Cashmere, India; Chas. Batchelor.

Boiler Explosions.—During the year ended June, 1890, only 21 lives were lost through boiler explosions in England. This is below the average for the last seven years, and, considering the great increase which must have taken place during that time in the total number of boilers working in that country, the tendency appears to be toward increased safety; at any rate, there are no facts which warrant the assumption of increased negligence on the part of steam-users.

ENGINE FOUNDATIONS.—An indicator card lately taken from a Westinghouse engine showed oscillations on all the lines, such as appear in the expansion line at higher speeds. The trouble was found to be in the spring of the foundation upon which the engine was set giving an oscillatory movement to the engine and which affected the indicator as well. This experience shows the necessity of solid foundations for engines.

FOR February, quicksilver shipments from Calistoga, Napa Co., were 722 flasks. Of this, the Napa Co. mine produced 310 flasks, the Great Western, 155, Bradford, 132, and the Sulphur Bank, 125.

The famous Breyfogle mine in Death Valley has again been discovered—for about the fiftieth time.

Fig. 6 - LOWER TERMINAL STRUCTURE, WITH COUNTER-WEIGHT ATTACHMENT.

Fig. 8 - ELEVATIONS AND PLAN OF UPPER TERMINAL.

The "Vulcan" Wire Ropeway.
(Concluded from page 177.)
mounted on steel splindles which are fastened on the hubs of the stands. The stands are made of cast iron and are fastened to the top of the cross-arms, the front end having lugs which span the width of the cross-arm timber. At the back end of the stand is an ohlong hole which permits of adjusting the sheave.
The guide-sheaves and stands (Fig. 3) are used at the terminals to guide the rope fair into the terminal sheaves and are used for station sheaves where the rope has a tendency to rise from its seat on the supporting sheave.
The clips are the most important attachments

Fig. 7 - END OF LOWER TERMINAL.

Figs. 10 and 11 - SUPPORTING STRUCTURES.

of a ropeway system, as on them depends the successful and economical running of the ropeway. The Vulcan patent inserted ropeway clip (Fig. 4) is made in two parts, B and C, which are connected with a pin, H, thus forming a hinge that opens upward. On the extreme end of the body, B (Fig. 4), is the spiral web A, which enters the rope. On the other end are two lugs, 8 and 9, drilled to receive the pin H (Fig. 5). The part C has on one end a round shaft; on the other end is the lip I that seats on the body B.
The spiral web A has corrugations 1, 2, 3, 4, 5 and 6. This spiral is made to conform to the pitch of the strands of the rope and to the size of its strands, so that the rope fits accurately in the corrugation. Fig. 5 represents the rope as it appears when the clip is inserted. Between the collars D and E goes the hanger which carries the load. The action of the clip on coming to a sheave is as follows: The body B comes in contact with the rim of the sheave, and is raised up as it travels over it. As it passes to the other side, it falls gradually until the lip I comes in contact with the body of the clip B. During all this operation the shaft C

of the clip remains in a horizontal position. The object of having the clip hinged is to provide an attachment for ropeways that will permit the use of deep and wide-grooved sheaves. Fig. 6 represents a side elevation of the lower terminal, the end to which the counterweight is attached. Fig. 7 is an end elevation of the same. The main frame on which is mounted the machinery is well framed and bolted and is furnished with a heavy set of car-wheels, H H (Fig. 6), which run on a flat iron track. At the extreme end of this track, which is long enough to take up the stretch of the rope, is placed the sheave L. The counterweight rope, K, passes over this sheave, one end being attached to the terminal structure, the other end to the weight receptacle, M. To a cross-arm, which is bolted to the main frame, back of the grip-sheave, is mounted a cast-iron frame that carries the guide-sheaves F and F. The terminal structure is encircled by a guide rail (Fig. 7), bolted to projecting arms. This is to prevent the conveyors snarling when turning around the terminals. To prevent accident, such as the terminal rising or running off the track, the top rail I (Fig. 6) is used. This is

set so that the car-wheels, H H, can run freely under it. At the point at which the material transported is to be discharged a permanent slip is placed, which releases the catches that hold the conveyor doors closed.
Fig. 8 shows the upper or loading end of the ropeway system on side and end elevation and plan. The construction of frame and mounting of the machinery is the same as on the lower terminal. On this terminal the track and counterweight are dispensed with, the frame being anchored to a good foundation made of masonry or of heavy logs of sufficient weight and stability to resist the strain put upon the rope. The ropeway is generally operated from this end. The brake to regulate

the speed at which it is desired the rope should travel is moved by the lever attached to the quadrant (elevation Fig. 8), and is operated from a platform which is bolted to the bottom of the main frame. This brake is only used when the line is a gravity one. When power has to be applied to run the rope, the brake-wheel is dispensed with, and in its place is put a bevel gear, driven by a pinion, to which power of any suitable character is applied. As the system is loaded at upper terminal, the brake attendant is always at this end.
Fig. 9 is an enlarged front elevation of the upper work or station structures. It is very substantial, being turned in every direction. When once set up it cannot get out of shape.
The supporting structures shown in Figs. 10 and 11 consist of wooden framework averaging about 15 feet in height. Their construction is easily seen by the cuts.
The grip-sheaves have been perfected from experience, and the clamping device is so arranged that there is no possibility of the seat splitting.
When large quantities of material have to be handled, a mechanical loader is necessary. The Vulcan patent loader, a very simple and effective device, will enable one man to load 20 to 40 tons of ore per hour. The shape and construction of the conveyors or buckets for transporting material are varied to suit different characters.
On one of the ropeways 10,115 feet long, with a difference of altitude of upper and lower terminal of 3575 feet, they carried 5900 cords of wood in nine months at a cost of 60 cents per cord, where it formerly cost \$2.20 per cord. In fact, taking into consideration additional items of freight, the ropeway system made a saving to the company in one year of \$33,583, after deducting the entire cost of the ropeway. With this system the delivery of ore or other material is not affected by rain or snow. The Vulcan Iron Works, 133-145 Fremont St., in this city, will give further particulars to any one desiring them.
IMPURE or second-grade paper pulp mixed with fuller's earth makes an excellent lagging for steam pipes.
MONTANA mining dividends for January and February of this year aggregate \$748,000.

Fig. 9 - UPPER WORK ON STATION STRUCTURE.

THE TECHNICAL WORKS

—OF—
CHARLES T. DAVIS.

A Practical Treatise on the Manufacture of Bricks, Tiles, Terra-Cotta, etc.—Including Hand-Made, Dry Clay, Tempered Clay, Soft Mud, and Stiff Clay Bricks, also Front, Hand Pressed, Steam Pressed, Re-Pressed, Ornamentally Shaped and Enamelled Bricks, Drain Tiles, Straight and Curved Sewer and Water Pipes, Fire Bricks, Fire Bricks, Glass Pots, Terra-Cotta, Roofing Tiles, Flooring Tiles, Art Tiles, Mosaic Tiles, and Tiles of various shapes and sizes, together with Enamelling in Polychrome Colors, Composition and Application of Glazes, etc., including Full Detailed Descriptions of the Most Modern Machines, Tools, Kilns, and Kiln Roofs used. By Charles Thomas Davis. Second Edition, Thoroughly Revised. 217 engravings, 500 pages. 8vo. Price.....\$5.00

A Treatise on Steam Boiler Incrustation, and Methods for Preventing Corrosion and the Formation of Scale. By Charles T. Davis. Illustrated by 65 engravings. 141 pages. 8vo. Price.....\$1.50

The Manufacture of Leather.—Being a description of all the Processes for the Tanning, Currying, Finishing, and Dyeing of every kind of Leather, including the various Raw Materials and the Methods for Determining their Values, the Tools, Machines, and all Details of Importance connected with an Intelligent and Profitable Prosecution of the Art, with Special Reference to the Best American Practice. By Charles Thomas Davis. Illustrated by 302 Engravings and 12 Samples of Dyed Leathers. 824 pages. 8vo. Price.....\$10.00

The Manufacture of Paper.—Being a description of the various Processes for the Fabrication, Coloring, and Finishing of every kind of Paper, including the different Raw Materials and the Methods for Determining their Values, the Tools, Machines and Practical Details. By Charles Thomas Davis. Illustrated by 180 engravings. 608 pages. 8vo. Price.....\$6.00

The above or any of our Books sent by mail, free of postage, at the publication prices, to any address in the world.

Illustrated circulars, showing full Tables of Contents of these books, sent free and free of postage to any one who will apply.

Our new and revised Catalogue of Practical and Scientific Books, 87 pages, 8vo, and our other catalogues, the whole covering every branch of Science applied to the Arts, sent free and free of postage to any one in any part of the world who will furnish us with his address.

HENRY CAREY BAIRD & CO.,
INDUSTRIAL PUBLISHERS, BOOKSELLERS AND IMPORTERS,
810 Walnut St., Philadelphia, Pa., U.S.A.

A Great Repository of Practical and Scientific Information.

One of the Fullest, Freshest and Most Valuable Handbooks of the Age. Indispensable to Every Practical Man.

NOW READY.
Price \$2.00.

Free of postage to any address in this world.

THE TECHNO-CHEMICAL RECIPT BOOK:

Containing Several Thousand Receipts, covering the Latest, most Important, and most Useful Discoveries in Chemical Technology, and their Practical Application in the Arts and the Industries. Edited chiefly from the German of Drs. Winkler, Klenze, Heintze, Mierzinski, Jacobson, Koller, and Heintze, with additions by Wm. T. Brandt, Graduate of the Royal Agricultural College of Eldena, Prussia, and Wm. H. Wahl, Ph.D. (Heid.), Secretary of the Franklin Institute, Philadelphia, author of "Galvanoplastic Manipulation." Illustrated by 78 engravings. One volume, over 500 pages. 12mo, elegantly bound in scarlet cloth, gilt, closely printed, containing an immense amount and a great variety of matter.

Price \$2.00, free of postage to any address in the world.

A circular of 32 pages, showing the full Table of Contents of this important Book, sent by mail free of postage to any one in any part of the world who will furnish his address.

MINING

Ore Dressing Machinery.

By C. G. WAMFORD LOCK.

CONTENTS.—Motive Power—Transmission of Power. Quarrying—Prospecting, Shaft-sinking, Coal-cutting, Pumping, and Ventilating Machinery—Lighting—Hauling and Hoisting Transport—Reducing—Dressing—Miscellaneous.

Price \$21.00. Circulars and Catalogues on application.

E. & F. N. SPON, Publishers,
12 Cortlandt St., New York.

The instrument represented in the above cut is a new and grand little invention, being designed to save life and limb, and innumerable lawsuits, by doing away with the dangerous operation of digging out wet and unexploded loads where Giant Powder is used in mining. The little instrument crimps the cap onto the end of the fuse firmly and absolutely water-tight. It is also used for cutting the fuse. They are neatly gotten-up of the finest cast steel, nickel-plated. Price, \$1.50 each.

N. W. MOODEY, Fresno, Cal.

TUBBS CORDAGE CO.

(A Corporation.)

Constantly on hand a full assortment of Manila Rope, Duplex Rope, Tared Manila Rope, Hay Rope, Whale Line, etc., etc.

Extra sizes and lengths made to order on short notice.

PACIFIC ROLLING MILL CO.,

.....MANUFACTURERS OF.....

Cast Steel Castings and Steel Forgings

UP TO 20,000 LBS. WEIGHT.

True to pattern and superior in strength, toughness and durability to Cast or Wrought Iron in any position or for any service.

GEARINGS, SHOES, DIES, CAMS, TAPPETS, PISTON-HEADS, RAILROAD and MACHINERY CASTINGS of Every Description.

—ALSO—

HOMOGENEOUS STEEL, SOFT and DUCTILE, SUPERIOR TO IRON FOR LOCOMOTIVE and MARINE FORGINGS.

ALSO Steel Rods, from 1/2 to 3 inch diameter and Flats from 1 to 8 inch. Angles, Tees, Channels and other shape Steel Wagon, Buggy, and Truck Tires, Plow Steel; Machinery and Special Shape Steel to size and lengths. **STEEL RAILS** from 12 to 46 pounds per yard. ALSO, Railroad and Merchant Iron, Rolled Beams, Angle, Channel, and T Iron, Bridge and Machine Bolts, Lag Screws, Nuts, Washers, Ship and Boat Spikes, Steamboat Shafts, Cranks, Pistons, Connecting Rods, etc. Car and Locomotive Axles and Frames, and Iron Forgings of all kinds, Iron and Steel Bridge and Roof Work a Specialty.

HIGHEST PRICE PAID FOR SCRAP IRON AND STEEL.

Orders will have prompt attention. Send for Catalogues. Address

PACIFIC ROLLING MILL CO., 202 Market St., San Francisco.

FULTON IRON WORKS,

HINOKLEY, SPIERS & HAYES, Proprietors.

(ESTABLISHED IN 1856.)

Office, 213 Fremont St.,

—MANUFACTURERS OF—

TUSTIN'S PULVERIZER.

MARINE ENGINES AND BOILERS.—Propeller Engines, either High Pressure or Compound, Stern or Side-wheel Engines.

MINING MACHINERY.—Hoisting Engines and Works, Cages, Ore Buckets, Ore Cars, Pumping Engines and Pumps, Water Buckets, Pump Columns, Air Compressors, Air Receivers, Air Pipes.

MILL MACHINERY.—Batteries for Dry or Wet Crushing, Amalgamating Pans, Settlers, Furnaces, Re-torts, Concentrators, Ore Feeders, Rock Breakers, Furnaces for Reducing Ores, Water Jackets, etc.

MISCELLANEOUS MACHINERY.—Flour Mill Machinery, Saw Mill Engines and Boilers, Dredging Machinery, Powder Mill Machinery, Water Wheels.

Tustin's Pulverizer

WORKS ORE WET OR DRY.

ENGINES AND BOILERS

OF ALL KINDS,

Either for use on Steamboats or for use on Land.

Water Pipe, Pump or Air Columns, Fish Tanks for Salmon Canneries

OF EVERY DESCRIPTION.

Boiler Repairs Promptly attended to and at very moderate rates.

AGENTS FOR THE PACIFIC COAST FOR THE

Deane Steam Pump.

SPECIALTIES:

Corliss Engines and Tustin Ore Pulverizers.

Agents and Manufacturers of the Llewellyn Feed Water Purifier and Heater.

ESTABLISHED 1866.

EVERETTE'S MINING OFFICE.

Pioneer Mining Office of the Northwest Coast.

Having the largest permanent brick assay furnaces, chemical laboratory and mining office on the Northwest Coast with a collection of about 400 samples of the ores of Alaska, British Columbia, Oregon and the Northwest Territories, and having made personal examinations of nearly every mining camp on the Pacific Slope, from California to Alaska, I am prepared to do any class of legitimate and honest mining work, such as EXAMINING, ENGINEERING, SAMPLING and REPORTING ON THE VALUE OF ALL MINERAL, COAL and FIRE-CLAY PROPERTIES, BUILDING STONES, EARTHES, ASSAYS AND ANALYSIS OF ORES, WATERS, OILS, ORE SAMPLES OF ORE, PULPS, "ORGANIC ANALYSIS" WORK, and in fact any work connected with the office of a first-class mining geologist and chemist. Any information mining men may desire to know relative to the MINERAL OR COAL RESOURCES of the entire Pacific Northwest will be honestly given. Address **Dr. Willis E. Everette** Consulting Mining Geologist and Chemist, 1318 E Street, Tacoma, Wash.

SOLE WESTERN AGENTS FOR TYLER WIRE WORKS DOUBLE CRIMPED MINING CLOTHS.

JAMES LEFFEL'S Mining Turbine Water Wheel.

These Wheels are designed for all purposes where limited quantities of water and high heads are utilized, and are guaranteed to give more power with less water than any other wheel made. Being placed on horizontal shaft, the power is transmitted direct to shafting by belts, dispensing with gearing.
Estimates furnished on application for wheels specially built and adapted in capacity to suit any particular case.
Further information can be obtained of this form of construction, as well as the ordinary Vertical Turbines for Wooden Penstocks and in Iron Globe Cases, free of cost, by applying to the manufacturers.

age, 10 cents. Postpaid to subscribers. Send no money, 50
cents. Send for illustrated circular. A circular post-
paid.

Mining Share Market.

Continued activity in Comstock mining shares marked the past week, with Best and Belcher making the best up move, although all other shares sold at higher prices. The advance in Best and Belcher is largely due to Con. Virginia arranging to take out the rich ore lying toward the former mine, which is likely to show up well in Best and Belcher. Besides this, the latter mine is doing some important work of its own, that, unless stopped, will develop rich ore to the west. An assessment by Hale and Norcross dampened the middle group mines shares. A reported pending assessment by Yellow Jacket, Con. Imperial and Bullion causes shares in the Gold Hill mines to move slowly. Confidence shares made quite an up move, but fell back as fast as they went up. There can be no doubt of the public lacking faith in the stability of the market, for all reports are confirmatory of there being more sellers than buyers, but some day this will be reversed—how soon, the writer cannot say. Everything at present warrants the belief that higher prices will obtain, for the manipulators appear to be (whether really so or not we are unable to learn) trying to get the public interested so as to unload to collect assessments while taking out bullion for themselves. The Alta group shares scored a slight advance the past week, with Justice the leader. In outside shares trading continues light, although the Bodies and Tuscaroras moved up slightly.

From the Comstock mines our advices report that on the 1100-foot level in Con. Virginia they cut 18 feet of ore going from \$60 to \$80 a ton. In Best and Belcher they are making good progress running for the ore lying to the west. News from the other North-End mines is of an encouraging character, and promises to be of an exciting nature before the close of the spring months. Between the Hale and Norcross and Savage mines important connections have been made, and now we can reasonably look for ore strikes, particularly since the former mine has levied another 50-cent assessment. On second thought, we are led to think that the managers of these two mines do not wish to make an ore development, but the work under way in Chollar lying south of Hale and Norcross, and in Gould and Curry lying north of Savage, may lead to rich strikes of ore next to or on the line of the mines, which would have the same effect as if they were made in Savage and Hale and Norcross. In Belcher they are cleaning out the old drifts drained by the pumps, with good results looked for when active prospecting work is inaugurated. In Overman the rich finds heretofore reported are confirmed by late advices received from Virginia City. In the other Gold Hill mines important work is under way. From the Bodies our advices report that eight stamps are dropping on Bodie ore, but official letters received yesterday do not mention the fact. Perhaps the bullion from the ore milled will be credited to another mine. The battery assays of Bulwer ore are higher, now going over \$40 a ton. From the Tuscaroras our advices are about as heretofore reported, as they are also from the Quijotas.

The mining share market opened this (Thursday) morning fairly active, at irregular prices. After regular Call, prices advanced slightly, but toward noon hour they were selling at about Call Board prices.

Confirmed advices from Virginia City report that more stamps will soon be dropping on Comstock. This is welcome news provided the bullion is not distributed among a favored few. Savage battery assays continue to creep up by small degrees. Con. Virginia's battery assays last week were slightly lower.

ON A RAILROAD STRUCTURE.

The Pennsylvania Railroad Co. is erecting at Jersey City an elevated railroad structure, over one mile long and four tracks wide, on which their entire passenger travel of millions of people will enter and leave the city. The iron work, which has 13 feet steel clearance, is immense in its proportions, and was made and erected by the Pencoyd Iron Works. It is a marvel of accurate and substantial construction. It has been the practice of the P. R. R. Co. heretofore to use a light colored paint on all of their iron structures, but after a thorough examination into the merits of Dixon's Silica-Graphite Paint they chose that as the paint for this work.

The work of painting is rapidly progressing, and Mr. Eckert, the superintendent of painting, says that, while he was at first very much opposed to the use of Graphite Paint, he now finds it is easily laid on, with a covering power twice that of white lead and three times that of other mineral paints, and of very handsome color.

The case with which this Graphite Paint is applied has been a subject of frequent comment among painters. Graphite in itself is an unequalled lubricant and when its lubricating quality is added to that of the oil it is not surprising that the painter can apply it with ease and comfort and wonder why he is not tired.

J. G. Allen, 304 Market street, San Francisco, is the Pacific Coast Agent.

Complimentary Samples.

Persons receiving this paper marked are requested to examine its contents, terms of subscription, and give it their own patronage, and, as far as practicable, aid in circulating the journal, and making its value more widely known to others, and extending its influence in the cause it faithfully serves. Subscription rate, \$3.00 a year. Extra copies mailed for 10 cents, if ordered soon enough. If already a subscriber, please show the paper to others.

Don't Fail to Write.

Should this paper be received by any subscriber who does not want it, or beyond the time he intends to pay for it, let him not fail to write us direct to stop it. A postal card (costing one cent only) will suffice. We will not knowingly send the paper to any one who does not wish it, but if it is continued through the failure of the subscriber to notify us to discontinue it, or some irresponsible party requested to stop it, we shall positively demand payment for the time it is sent. LOOK CAREFULLY AT THE LABEL ON YOUR PAPER.

DIAMOND DRILLS

THE PACIFIC PROSPECTING CO. will contract to prospect with Diamond Ore Drill for minerals, etc., or to bore holes for ventilation or drainage. Agents for Diamond Drills, Rock Drills, Mining Machinery and Supplies of all kinds. Diamond on hand. Inquiries and orders promptly attended to. 213 Sansome Street, San Francisco, Cal.

New Incorporations.

The following companies have been incorporated, and papers filed in the office of the Superior Court, Department 10, San Francisco:

INTERNATIONAL TRANSIT LINE (Oakland), March 13. Object, to transport vegetables, fruit, grain, and merchandise of all descriptions to all parts of the United States and throughout the civilized world. The company will also own its own rolling-stock and deal in real estate for its own warehouses, negotiate loans, etc. Capital, \$1,000,000. Directors—W. P. Jones, V. D. Moody, H. Sevensing, J. M. Bailey and J. R. Lanktree.

ACME BUILDING AND LOAN ASS'N., March 14. Capital stock, \$100,000. Directors—S. J. Aschheim, Chas. J. Simon, A. P. Otto, S. B. Schloss, Jacob Heyman, David Davis and R. P. Hurlburt.

AMERICAN FUEL-SAVING CO., March 16. Capital stock, \$1,000,000. Directors—Peter Abramson, W. W. Montague, A. M. Loryea, Julius Jacobs and E. M. Reading.

CALIFORNIA FRUIT EXPRESS CO., March 17. Capital stock, \$1,000,000. Directors—J. S. Whitcomb, E. E. Avery, W. M. Ott, C. H. Brookman and P. S. Deincer.

PIONEER PAPER MILL CO., March 17. Capital stock, \$500,000. Directors—Sarah J. Taylor, Edwin M. Taylor, Samuel J. Taylor, W. P. Taylor, and James I. Taylor.

TUOLUMNE RIVER QUARTZ M. CO., March 18. Capital stock, \$120,000. Directors—A. B. Cruikshank, Jabez Howes, John A. Magee Jr., John Frace and J. W. Burling.

VENTURA CRYSTAL PLASTER CO., March 18. Capital stock, \$350,000. Directors—W. E. Sharp, W. E. Atwater, H. B. Sharp, A. H. Hall and G. H. Wheeler.

JUSTICE BUILDING AND LOAN ASS'N., March 18. Capital stock, \$3,000,000. Directors—Simon Solomon, Chas. C. McDonald, Frank A. Lux, Wm. Osterman, B. J. Sideman, G. Conn, Chas. J. Simon, R. Goldfish and Jules Marzbach.

BACK FILES OF THE MINING AND SCIENTIFIC PRESS (unbound) can be had for \$3 per volume of six months. Per year (two volumes) \$6. Inserted in Dewey's patent binder, 50 cents additional per volume.

Assessment Notices.

CRESCENT MILL & MINING COMPANY. Location of principal place of business, San Francisco, California. Location of works, Crescent Mill, Plumas County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on Friday, the 20th day of February, 1891, an assessment (No. 5) of Twenty-five cents (25c) per share was levied upon the Capital Stock of the Corporation, payable immediately in United States gold coin to the Secretary, at the office of the Company, No. 310 Pine Street, Room 40, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 6th day of April, 1891, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on MONDAY, the 4th day of May, 1891, to pay the delinquent assessment, together with the costs of advertising and expenses of sale.

By order of the Board of Directors.
J. H. ISHAM, Secretary,
Office, No. 310 Pine Street, Room 40, San Francisco, California.

DELINQUENT SALE NOTICE.

GRAY EAGLE MINING COMPANY—Location of principal place of business, San Francisco, California. Location of works, Placer county, California.

Notice—There are delinquent upon the following described stock, on account of Assessment (No. 2) levied on the 4th day of February, 1891, the several amounts set opposite the names of the respective shareholders, as follows:

Name.	No. Cert.	No. Shares.	Amt.
Barrows, A. W., Trustee.....	556	271	\$ 8 13
Francis, H. L., Trustee.....	444	1,600	45 02
Horton, T. R., Trustee.....	665	2,500	75 00
Lane, Mr. Sarah, Trustee.....	365	200	6 00
Stout, C. N., Trustee.....	477	953	28 50
Scarlee, W. A., Trustee.....	618	1,000	30 00

And in accordance with law, and an order of the Board of Directors, made on the 4th day of February, 1891, so many shares of each parcel of such stock as may be necessary, will be sold at public auction, at the office of the Company, Room 11, No. 308 California street, San Francisco, California, on MONDAY, the 30th day of March, 1891, at the hour of one (1) o'clock P. M. of said day, to pay said delinquent assessment thereon, together with costs of advertising and expenses of the sale.

A. W. BARROWS, Secretary pro tem.
Office, Room 11, No. 308 California street, San Francisco, California.

Iron cut, punched and formed, for making pipe on ground. All kinds of Tools supplied for making Pipe. Estimates given. Are prepared for coating all sizes of Pipe with a composition of Coal Tar and Asphaltum.

About Obtaining Patents.

Patents are Virtually Contracts.

The Patent Law provides that in case a patent, which is the evidence of the contract, is not executed in compliance with the requirements of the law, it may be annulled and rendered void. Hence it is of the greatest importance to every inventor that his patent or contract be skillfully and accurately drafted, in order that it may afford him complete protection for his invention during the life of his patent.

How to Procure a Patent.

To avoid all needless delay, however, and secure patents at the earliest moment practicable, inventors will do well to forward a model, drawing or sketch, with a plain, full and comprehensive description of their invention (stating distinctly what the particular points of improvement are), with \$15 as a first installment of fees. If the improvement appears to us to be novel and patentable, the necessary papers for an application for a patent will be prepared immediately and forwarded to the inventor for his signature. When he receives the application and finds it duly prepared, he will carefully sign and return the same plainly addressed to us, with postal money order or express receipt for our own fee. The case will then be promptly filed by us in the Patent Office, and vigorously prosecuted to secure the best patent possible. [This course is the most expeditious and satisfactory, as no time is lost in transmitting correspondence relative to the preliminary steps.] When the patent is allowed, the inventor will be duly notified, and on sending the final Government fee of \$20 to us, we will order the issue of the patent, and forward the same as soon as it is secured from the Patent Office.

The payments are thus divided and made easy. We make no pretense of doing cheap work, in order to entice custom, nor do we afterward make additional charges to bring the bill up to a fair compensation. We do our work honestly and thoroughly, and we never give up a case so long as there is a chance of obtaining a patent. The Agency charge, including drawings, rarely exceeds \$40, and for this we do all we can without appealing the case.

Models and Drawings.

Models are now seldom required by the Commissioner of Patents, and generally only in intricate cases. Perfect drawings of practical working machines are more satisfactory to the Patent Office than the old cumbersome system of storing up an immense bulk of countless models.

Drawings or sketches, sufficient to illustrate the invention clearly, with a description that will enable us to make a full set of perfect drawings for the Patent Office, is all that we require. A model will answer our purpose as well, however, in cases where the inventor can more easily furnish it.

Secure a Good Patent.

The value and even the validity of a patent often depends on the character, clearness and sufficiency of its drawings. There are thousands of existing patents in which the improvements are but partially or poorly illustrated in the drawings. When an attempt is made to dispose of such patents, the vagueness and defects of the drawings often prejudice capitalists and manufacturers against the invention, while in reality it may be of great value, and would meet with ready sale had it been skillfully, completely and artistically portrayed. In all cases prepared by us, the drawings are made under our personal supervision, by skilled draftsmen in our constant employ, and every precaution is taken to have the invention fully and clearly shown by different views, so that the improvement will be readily understood by the Examiners in the Patent Office, and comprehended by the public when the patent is granted.

Advantages to Inventors on the Pacific Coast.

The firm of DEWEY & CO. has edited and published the MINING AND SCIENTIFIC PRESS continuously since 1850—a period of 39 years. Few agents, who are still engaged in the business, have had so long-extended practice in patent soliciting. The members of the firm give personal attention to the applications entrusted to their care; and their familiarity with inventions and with local affairs in the Pacific States and Territories enables them to understand the wants of inventors on this coast more readily and thoroughly as we believe, than any other agents in America. Thus there is saved a great deal of the time which ordinarily, when distant agents are employed, is wasted in preliminary writing back and forth.

This happy combination of long business experience together and wide connections has placed our firm in a position unquestionably most fortunate for affording inventors prompt and reliable advice, and the best facilities for securing their full patent rights with safety and dispatch at uniformly reasonable rates.

Every patentee of a worthy invention is guaranteed the gratuitous publication of a clearly stated and correct description of his invention, in one or more of our influential and reliable newspapers, affording just the circulation best calculated to widely inform the class of readers especially interested in the subject of his invention.

Caveats.

A Caveat is a confidential communication made to the Patent Office, and is therefore filed within its secret archives. The privilege secured under a caveat is that it entitles the caveator to receive notice, for a period of one year, of any application for a patent subsequently filed, which is adjudged to be novel and is likely to interfere with the invention described in the caveat, and the caveator is then required to complete his application for a patent within three months from the date of said notice. Caveat papers should be very carefully prepared. Our fee for the service varies from \$10 to \$20. The Government fee is \$10 additional.

To enable us to prepare caveat papers, we require only a sketch and description of the invention.

Rejected Applications.

Inventors who have rejected cases (prepared either by themselves or for them by other agents) and desire to ascertain their prospects of success by further efforts, are invited to avail themselves of our unrivaled facilities for securing favorable results. We have been successful in securing Letters Patent in many previously abandoned cases. Our terms are always reasonable.

Inventor doing business with us will be notified of the state of their application in the Patent Office whenever it is possible for us to furnish such information.

Protected by Patents December 22, 1874; September 2, 1879; April 27, 1880; March 22, 1881; February 20, 1883; September 18, 1883; July 24, 1888. Patents applied for.

There are Over 2200 Plain Belt Machines now in Use.

THE MONTANA COMPANY (Limited), London, October 8, 1885.
DEAR SIR:—Having tested three of your Frue Vanners in a competitive trial with other similar machines (Triumph), we have satisfied ourselves of the superiority of your Vanners, as is evidenced by the fact of our having ordered 20 more of your machines for immediate delivery. Yours truly, THE MONTANA COMPANY (Limited).

N. B.—Since the above was written the 20 Vanners, having been started, gave such satisfaction that 44 additional Frues and more stamps have been purchased. ADAMS & CARTER.

"TRIUMPH" ORE CONCENTRATOR WITH IMPROVED RIFFLED BELT.

The competitive trials which have been held between the "Triumph" Ore Concentrators, the "Frue" Vanners and other forms of concentrating devices, do not warrant the assertion that the "Frue" Vanner is the best ore concentrator in the market. The fact that the "Frues" have improved (corrugated) belts does not militate against the superiority of the "Triumphs;" for, when desired, they (the "Triumphs") can be mounted with a superior belt known as the "Blasdel" Riffled.

Price "Triumph" Concentrators, with Improved (Patented) Belt - - - \$650 f. o. b.
Price "Triumph" Concentrators, with Plain Belt - - - - - \$550 f. o. b.

We are prepared to guarantee the superiority of the "Triumph" over the "Frue" or any other form of Concentrator, for coin it need be. Circulars and testimonial letters furnished on application.

JOSHUA HENDY MACHINE WORKS,

39 to 51 Fremont Street, San Francisco, Cal.

(PATENTED.)
Both the "Triumph" Concentrator and "Blasdel" (riffled) Belt are protected by incontestable letters patent, granted by the Government of the United States.

GRASS VALLEY, NEVADA Co., CAL., Nov. 10, 1885.

Joshua Hendy Machine Works, 39 to 51 Fremont St., S. F., Cal.:
GENTLEMEN—I am pleased to state, in reference to the "Triumph" Ore Concentrators, that four (4) of them were placed in the mill of the Original Empire Mill and Mining Company in April, 1884, and a thorough test made of their practical operation; and their efficiency having been demonstrated, four (4) more were subsequently introduced as the complement of the Twenty (20) Stamp Mill, and the eight (8) have been and are now running with entirely satisfactory results.

At the Ten (10) Stamp Mill of the North Star Mining Company, under my supervision, four (4) are also in successful operation, and from my observation of their practical workings, I am convinced that in form of Concentrators is the equal, if not superior to any other style of Vanners or concentrating devices. DAVID McKAY, JR.,
[Signed] Sup't North Star and Original Empire Mining Co.
N. B. When the stamping capacity of the two above named mills was increased, more "Triumph" Concentrators were purchased, and twenty-eight (28) are now in constant successful operation.

JOSHUA HENDY MACHINE WORKS,

Nos. 39 to 51 FREMONT STREET, SAN FRANCISCO, CAL.

"HENDY" IMPROVED "CHALLENGE" ORE FEEDER

The best form of Feeder ever devised, and pronounced by reputable mining men to be far superior to any form of "Roller" Feeder manufactured. We refer to the following gentlemen who have furnished us with testimonial letters to the above effect, which can be seen at our office, viz.:

N. W. CROCKER, Supt. Banker Hill Gold Mining Co., Amador City, Cal. D. O. WICKHAM, Taylor Mine, Greenwood, Cal.
J. R. TREGLOAN, Supt. South Spring Hill Gold Mining Co., Amador City, Cal.

The Dodge Sampling Machine.

The sampling machine illustrated on this page, will save a vast amount of labor and floor space, and will sample ores much more

correctly than can be done by hand. For large sample works a No. 2 machine is used for coarse material and a No. 3 for resampling the products of No. 2. The No. 3 machine can be set to crush very fine, and is very valuable to

such mines as sack ore for long shipment, as fine ores will not cut the bags, and at the same time an invariably correct sample is taken for assay.

As shown by the accompanying cuts, the mechanism that works the sampler is driven by a belt from the shaft (8) of the crusher to an auxiliary shaft (28) on which is a drum (21). On one side of the drum is a stationary stud (24) with a revolving ring, while on the opposite side is a stud (23) with a revolving ring

Concentrating California Tin Ore.

Report of a Competitive Trial of Concentrators.

The Frue vanner is a well-known machine for handling precious-metal ore, but has only now been applied to the concentration of tin ores, with which it has been found to be equally successful. With gold ores in many cases three ordinary Frue vanners to ten stamps will yield entirely satisfactory

THE DODGE ORE-SAMPLER

FRUE VANNER USED IN CONCENTRATING TIN ORES.

which is adjustable to ten holes (20), thus regulating the amount of the sample to be taken. These studs and rings revolve in an oil basin (22) which provides perfect lubrication, and in revolving strike the cam (19) which turns the "deflector" (14) from one side to the other, thus diverting the exact proportion of sample desired, as previously determined by the adjustment.

By changing the stud and rings a perfect sample is obtained, varying in quantity from one-tenth to one-half of the total amount of ore fed to crusher. This is one of the patents of M. B. Dodge now controlled and manufactured by the Parke & Lacy Co., 21 and 23 Fremont St., in this city.

work, and where the gangue is light, or the stamps not heavy, one Frue concentrator treats all the ore crushed with five stamps, and does perfect work; e. g., in the Empire Mill of 80 stamps (the property of the Plymouth Consolidated Gold M. Co. of Amador county, Cal.), 16 Frues are concentrating all the ore crushed by the 80 stamps. They are doing perfect work; the tailings assay merely a trace. In the 40-stamp mill of the Melones Consolidated Gold Mining Company of Calaveras county, Cal., eight Frue vanners are treating all the ore; the tailings assay nothing. But in order to be sure of low tailings, two of these machines are generally put to five stamps.

There are two styles of Frue vanners manufactured that handle five stamps each, or from 12 to 18 tons per day, and do it satisfactorily. One is the four-foot-wide Morse or Improved Belt Frue. This machine is doing double the work of the ordinary machines in many mills. At the Bailey Elkhorn mine it is handling 12 tons per day very easily. The other is the six-foot-wide plain belt machine. At the Standard mill, Bodie, four of these machines are handling satisfactorily from 60 to 70 tons per day. There are nearly 100 of these two styles of machines in use. Of the regular style Frue vanner there have been 3000 sold.

In concentrating tin ores in Cornwall with jigs and buddles, the ore must pass through the machines several times before it comes to the condition of "black metal" suitable for smelting. Experiments just made at the San Jacinto tin mines, San Bernardino county, prove that with the proper machines one concentration is sufficient to prepare the ore. The report of the competitive trial between the Frue and Woodbury concentrators on this tin ore will show the results accomplished. Following is a copy of the report:

CAJALCO, March 3, 1891.

Mr. E. N. Robinson, General Manager San Jacinto Estate, Ltd., Cajalco, Cal.—MY DEAR SIR: We started our test-mill on January 29th. The number of the screen at the battery was a No. 8, equal to a 32-mesh screen.

The Frue was the concentrator used. The concentrates yielded 66 per cent of tin metal. The tailings were sampled and tested, and were found to contain per ton of tailings, 11 lbs. cassiterite (yielding 70 per cent tin metal), equal consequently, to 7.7 lbs. of tin metal.

Nearly all the slime has been saved by this machine, and the greater part of the loss was found in the coarse tailings. I naturally came to the conclusion that the screen was too coarse for close

SECTIONAL VIEWS OF DODGE CRUSHER AND ORE-SAMPLER.

(Continued on page 201.)

CORRESPONDENCE.

We admit, unindorsed, opinions of correspondents.—EDS.

South African Gold Fields.

Description of the Johannesburg Region.

EDITORS PRESS:—In the issue of your journal of December 13, 1889, I find a paragraph headed "The South African Gold Fields," relating to this place and the gold industry of these fields, which is calculated to convey a very erroneous impression, not only as to the conditions under which we live here, but also as to the importance of the gold discoveries themselves.

I may say that I am myself a native of America and came here four years ago. I am well acquainted with these fields, and, as my experience while in America was all in connection with mines and mining, I do not speak in ignorance in what I have to say as to this place.

The gold belt (i. e., what is known as the Main Reef series) extends for 30 or 40 miles, the town of Johannesburg being situated about the middle of the line, and the gold is deposited (with singular evenness) throughout, in what are known here as "banket" reefs, but which technically are deposits of conglomerate (cement). The value of these reefs varies at different parts of the line, but the milling results at all the mines (and there are some 1400 beads of stamps at work) for the whole of last year gave an average yield of 13½ dwts. per ton of rock crushed. As the mining work necessary is simple and inexpensive, averaging somewhere between six and seven dwts., the margin of profit is large.

In criticizing these fields, it must not be forgotten that their very existence was unknown and their place represented by open, uninteresting prairie four or five years ago. As the population was at that time without any experience of mining, the incompetence of those who first took the development of these reefs in hand was simply monstrous, and the place still suffers from their extravagance and ignorance. The disadvantage of amateur mismanagement was added to by the extreme isolation of the place, lying as it did over 400 miles from the nearest seaboard and over 300 from the nearest railway line. Thus, all the supplies for the mines, and for the support of the immense number of people who quickly collected here, had to be brought along tracks, not deserving the name of roads, by ox-wagon, thus making every necessity expensive and adding enormously to the cost of mining. However, railways are nearing us from all the ports of South Africa. We have a fine town with substantial stone and brick buildings two and three stories in height (both public and private), churches and schools well attended, and all the accessories of the most advanced civilization. Men have their wives and families here, and these are as safe from insult or interference in the public streets as at any American town or city. At no time was there at Johannesburg any semblance of the lawlessness, vice and disorder that characterizes most American towns, as as your paragraph inferred. Any man who carried a revolver here would be subjected to such a round of chaff and practical jokes that he would soon be glad to leave the weapon round home. As for gambling-hells, the police of the State would soon break up any that opened their doors. My personal acquaintance with many American mining-camps, as some of your readers will probably know, has been long and varied, and I unhesitatingly aver that Johannesburg never bore any trace of resemblance to them.

As some of your readers may take more than a passing interest in this new El Dorado, I have obtained and inclose you the official returns of the Witwatersrand Chamber of Mines for last year. [See editorial pages.—EDS. PRESS.] These will show that the presence of gold in quantity here is actual; that that gold can be profitably worked is shown by the regular monthly dividends some of the companies are paying. £165,000 sterling, i. e., \$825,000, was paid away in dividends to shareholders last month.

This is surprising even to me in face of the fact that most companies of these fields were floated in "boom" times at capitals that more than half went to vendors, promoters and brokers. Our output for last month will be between 52,000 and 53,000 ounces. It progressed in 1890 from 35,000 to 50,000, and in 1891, with new batteries on well-developed mines being completed all along the line, it shows every promise of increasing from 50,000 to 70,000 ounces.

These reefs, your readers must bear in mind, are not quartz reefs, rich in one place and barren in another, but bear gold regularly throughout their 36 miles of length. They are proved to 700 feet in depth by prospecting workings and by the diamond drill and there is every indication that they continue indefinitely. So far as my knowledge, both personal and from books of authority, extends, there is nothing like it in the world, and this vast mining area has up to the present been, figuratively speaking, merely scratched. The fields offer perhaps as great facilities as any other in the world for the profitable investment of capital, and it is and has been a matter of regret to me that Americans have not had a larger share in the

profits which have accrued to those concerned in the advancement of the place.

It is not however, too late, for the enormous capabilities of the banket formation are yet only on the threshold of exemplification, and I write this somewhat lengthy letter chiefly in the hope that your remarks may not lead my countrymen to suppose that this place is a humble city that will burst ere it is yet formed, or deter them from obtaining interests in the many good things the Witwatersrand fields holds out.

I trust you will be able to find room for this, I fear, rambling effusion. I may in conclusion say that your estimable journal is read here with great interest, not alone by Americans, but by many deep-thinking men of other countries, who are interested in mining.

C. R. KEHLER

Johannesburg, South African Republic, Feb. 6, 1891.

Facts About Weather Forecasts.

The Pacific Branch of the National Weather Service.

Lieut. John P. Finley, in charge of the Division of the Pacific Signal Service, U. S. A. has issued a bulletin giving the following facts about weather forecasts in this region:

The branch office of the National Weather Service, Division of the Pacific, was opened at San Francisco, March 1, 1885, and is the only office of its kind in the country outside of the central office at Washington, D. C. It was established for the purpose of providing, in the most direct and practical manner an opportunity for the people of the Pacific Coast to receive all of the benefits that may be derived from the work of the Signal Service. The main object was to prepare and distribute through the press and by telegraph, weather forecasts for the Pacific Coast States, and warn vessels of the approach of storms dangerous to shipping off the coast. Also, to make special forecasts of rain, frosts, floods and local storms. Such work had been carried on at the central office at Washington many years for the eastern portion of the United States, and it was believed that the time had come for the organization of a Pacific Coast Weather Service, with headquarters at the metropolis of the coast, and at a place centrally located for the convenient receipt and distribution of telegraphic reports. To properly apply the weather forecasts to definite areas of country, the Pacific Coast was divided into three districts, designated officially as follows: North Pacific region (embracing Western Oregon and Western Washington), Middle Pacific region (embracing the western portion of California, north of parallel 37 degrees north, or an east and west line cutting the northern edge of the bay of Monterey), South Pacific region (embracing the western portion of California south of parallel 37 degrees north). On May 1, 1886, an order was issued from Washington changing the districts to State areas, and thereafter the weather forecasts were made for the following regions: Washington (embracing the entire State), Oregon (embracing the entire State), Northern California (embracing that portion of the State north of the latitude of 36 degrees, or an east and west line passing through the central portion of Lake Tulare). Southern California (embracing that portion of the State south of the latitude of 36 degrees. There have been several changes in the hours at which the forecasts have been prepared for issue, dependent upon the hours of meteorological observation and the convenience of the press. Observations are now taken throughout the United States at 8 A. M. and at 8 P. M., 75th meridian time, which corresponds to 5 A. M. and 5 P. M., Pacific time. The weather forecasts are issued from the San Francisco office about 9:30 A. M. and 6:30 P. M. daily. An earlier hour cannot be selected because of the want of telegraphic facilities in concentrating the reports at San Francisco from all parts of the Pacific Coast States. The language of the forecasts must largely conform to the official instructions issued from the central office at Washington.

Forecasts of higher or lower temperature are made each morning with reference to the expected minimum temperature of the following morning, and each evening with reference to the maximum temperature expected on the following afternoon. The forecasts of stationary temperature indicate a change of four degrees or less from March to October inclusive, and six degrees or less for the remaining months of the year. In the case of higher or lower temperature a change of one degree or more is sufficient to verify the forecast. A cold wave, in general terms, is defined to be a fall in temperature over an extensive area of 20 degrees in 24 hours, or 28 degrees in 48 hours and to the freezing point or below. Warnings of cold waves are issued when it is expected that the area affected will exceed 100,000 square miles in extent, and in well defined cases for a lesser area. Forecasts of fair weather mean an entire absence of rainfall, but not necessarily an absence of clouds. Forecasts are usually made for a period of 24 hours, but whenever the meteorological conditions are so decided as to dominate the present, and are expected to materially modify coming weather over any extensive part of the country, forecasts may be made for periods of 36, 48 and 72 hours. Generally speaking, it is more difficult to forecast accurately the weather of summer than that of winter, because of the absence in the former season

of well-defined storm centers, most of the precipitation being the result of local changes in temperature and wind direction. For a similar reason it is more difficult to forecast the changes of a moderate storm than of those which attend a severe one, because in the latter case the laws of cyclonic development and progression are more closely adhered to, which permits the principle of weather forecasting to be applied with greater success.

Irrigation in Arizona.

The following is the introductory portion of a census bulletin by F. H. Newell, for which we are indebted to C. C. Babb:

The total area in Arizona on which crops were raised by irrigation in the census year ending June 30, 1890, was 65,821 acres, or 102.8 square miles, less than one-tenth of one per cent of the entire area of the Territory. The aggregate number of farms was 1448, and of these 1075, or 74 per cent, depended upon irrigation, the remaining 26 per cent being stock ranches, or farms situated high in the mountains, where crops can be raised by what is known as "dry farming." The average size of irrigated farms, or rather of the irrigated portions of farms on which irrigation was practiced, was 61 acres. In this connection the term "irrigated farm" is used to include only the area on which crops were raised by irrigation, the noncultivated portions of such farms not being taken into account. With this understanding the irrigated farms or areas cultivated by each person have been classified as follows: Seven irrigated farms of 640 acres or upward, 15 of from 320 to 640 acres, and 57 of from 160 to 320 acres. These 79 farms contain an average of 237 acres each, and have a total area of 22,656 acres, or 34 per cent of the entire amount watered in the Territory. The remaining 996 farms, under 160 acres in size, comprise only 66 per cent of the total irrigated area, and average 43 acres each. In other words, seven per cent of the farmers of the Territory owned over one-third of the productive land, and the remaining 93 per cent of irrigators owned an average of 43 acres each.

Counties.	Number of irrigators.	Total irrigated area in crop, acres.	Average size of irrigated farms in products, per acre.
Apache.....	182	5,545	30
Cochise.....	52	2,372	46
Gila.....	18	815	46
Graham.....	199	7,656	38
Maricopa.....	327	35,212	108
Pima.....	85	3,085	36
Pinal.....	115	6,010	51
Yavapai.....	91	3,762	41
Yuma.....	6	555	93
Total.....	1,075	65,821	61

Taking all the counties in the Territory, with their varying conditions, the average cost of water right was \$7.07 per acre. This includes all cases, from the one extreme, in which the farmer dug his own ditches from the river—the cost of water right in that case being the amount which the ditch cost him in labor and material—to the other extreme, in which he purchased his water right from some company, paying a certain sum per acre for the privilege of renting or buying water each year. The selling value placed upon this by the farmer, whenever his right was transferable, was \$12.58. The average annual cost for water was \$1.55 per acre, this expenditure being either in labor in keeping the main ditches and dams in repair or paid as a cash assessment or rental to an association or corporation.

Besides the first cost of the water and the annual assessment for its use, an estimate has been made of the first cost of bringing the land from a wild state under cultivation by irrigation beyond the expense for the water right. This estimate, which is \$3.60 per acre, includes the cost of plowing, grubbing sagebrush, cutting mesquite, fencing and leveling, or otherwise preparing the ground for irrigation.

Assuming, then, that the original purchase price of the land was \$1.25 per acre, the cost of preparing for cultivation by irrigation \$3.60 per acre, and the first cost of water right \$7.07 per acre, the land cost the original owners a total of \$16.92 per acre. It is ascertained, for comparison with this, that the average valuation, including buildings, fences and other improvements of the land on which irrigation is practiced, is placed by the owners at \$48.68 per acre, showing an apparent profit, less cost of buildings, of \$31.76 per acre.

In comparison with the annual outlay for water, it is found that the average annual value of farm products is \$13.92 per acre, leaving the farmer \$12.37 per acre per annum as a return for his labor and as interest on his investment.

The agricultural and irrigable land of Arizona is situated in the southwestern half of the Territory. If a line be drawn from the northwestern to the southeastern corner diagonally across the Territory, this line will lie for a greater portion of the distance along the face of the great escarpment which divides the high plateaus from the plains of the Gila basin. Against the face of this escarpment the larger portion of the available moisture is precipitated, rolling back to feed the tributaries of the Gila, thus rendering possible a certain amount of irrigation in the narrow valleys, especially on the Gila and Salt river plains near the point where their waters leave the canyons. High up on the edge of the plateau country and among the mountains, at elevations of from 5000 to 7000 feet, a little agriculture is successfully carried on without irrigation, usually

in connection with stock-raising or in the immediate vicinity of mining towns. The crops raised, however, are comparatively insignificant.

The acreage at present under irrigation may be regarded as approaching the maximum possible with the present supply of water and methods of using it. In other words, all the easily available water has been utilized, and expansion can come only by a greater economy in the use of the existing supply or by the adoption of systems of storage for the conservation of the flood-water now annually running to waste. The irrigators look forward to the latter alternative as the most effectual means of obtaining relief from present troubles and uncertainties. Progress in this direction will, however, be slow, from the necessity of a large outlay of capital before any return can be realized, and from the fact that the controllers of capital, whether governmental or private, have had comparatively few facts on which to base reliable estimates. The amount of water that can be reserved by storage is known from common observation to be very large, but it is usually greatly overestimated, from the fact that even a small volume of water, coming all at once and with great velocity, is often extremely destructive and creates a vivid impression, while the same amount, if distributed through as many days or weeks as it is hours, would not excite comment. Measurements have been made in a few instances by engineers and by the United States Geological Survey, but the operations of the latter were discontinued before a range of mud over a year had been obtained. For example, taking what is probably the best storage site in Arizona, that on the Gila at the Bottes above Florence, the mean discharge at this place, as shown in the eleventh annual report of the Director of the United States Geological Survey, from September 1, 1889, to August 31, 1890, when operations were suspended, was 503 second-feet, averaging 1000 acre-feet per day, or 365,000 acre-feet for the whole year. Assuming a water duty of 100 acres to the second foot, this, if all the water could be stored, would irrigate 50,000 acres, instead of the 7000 acres or less now irrigated in the vicinity of Florence. A large reduction from this theoretical amount must, however, be made for losses by evaporation and seepage. Without going into a discussion of the measured water supply, this will suffice to show that it is possible to determine the volume and intensity of floods, and that when this has been done the water-storage problem will be in a fair way to solution, since only then will it be possible to prepare reliable estimates of costs and profits.

Resources of Alaska.

In concluding a long report upon the wealth and resources of Alaska, Special Agent Petroff of the Census Bureau, in a bulletin just issued, speaks as follows: "In this survey of the wealth and resources of Alaska the observer is struck with one rather discouraging feature—that all those vast resources, the products of land and sea, are taken out of the country without leaving any equivalent to the inhabitants. The chief industries, such as salmon canneries, cod fisheries, mules and the fur trade, are carried on with labor imported to Alaska and taken away again, thus taking out of the country the wages earned. Every pound of subsistence for those laborers, as well as all the clothing they use, is carried by them into Alaska.

"The shipping of Alaska, which has become of considerable value, is also carried on wholly by non-residents of the Territory, chiefly from California, Oregon and Washington, and this state of affairs extends even to the important tourist travel to the southeastern district of Alaska. Not only the passage money, but the whole cost of subsistence of these tourists during their stay in Alaska, goes to the California owners of the steamship lines. To give an idea of the magnitude of this traffic it is only necessary to state that the number of tourists' tickets sold each season exceeds 5000, each ticket representing an expenditure of not less than \$100, making a total of \$500,000. The insignificant payment for fire and labor to natives are absorbed entirely in the purchase of small quantities of food and raiment.

"The spectacle of so vast a tract of country being thus drained continually for 23 years without receiving anything to speak of in return cannot probably be equaled in any other part of the United States, and perhaps of the world. At the same time the only prospect for a change in these circumstances, by immigration and settlement of people, who could supply the demand for labor and develop the industries as residents of the country, would appear to be still in the far distant future."

COAL RECEIPTS.—The receipts of coal so far this month have averaged 4000 tons a day or 1000 tons a day in excess of the consumption. The receipts for last month averaged 5000 tons a day. A large number of cargoes are on the way here from different ports.

THE last report of the Chicago City Railway shows that on its line the operating expenses a horse-car mile were 21.95¢ cents, and a cable-car mile 9.65¢ cents. The company ran 12,740,480 cable-car miles and 4,859,200 horse-car miles.

Romneya Coulteri.

[Written for the Press by C. R. ORCUTT.]

One of the most charming of California wild flowers is the large, perennial white-flowered poppy, *Romneya Coulteri*, which has been favorably known abroad for many years, and has in recent times been rediscovered, so to speak, by California.

The genus was named *Romneya*, in honor of the Rev. Dr. T. Romney Robinson, a noted astronomer of Armagh. It is a shrub, usually from 5 to 15 feet in height, half-woody at base and does not die down but needs to be pruned well back in the fall. It is one of the finest of California plants. In early spring vigorous shoots start from the dormant roots and grow from 6 to 10 feet high. The large hairy buds open at daylight; the crimped petals slowly unfolding from over the huge bunch of stamens (the bunch as large as a walnut) until they spread out from 6 to 9 inches. They last several days, the buds opening well in water.

The foliage is very effective, and makes with the flower a very beautiful and artistic study. There is a delightful harmony between the much-divided glaucous foliage and the waxy-white flowers, which make it much admired as a decorative plant.

The *Romneya* occurs from Santa Barbara county, southward into San Bernardino and San Diego counties, and below the Mexican boundary nearly to San Quintin bay, Lower California. It is seen at its best in San Diego county and in Lower California, where it may be found growing along the borders of streams, in the richest and most fertile portions of our valleys, or on the dry mountain or hillsides and in sheltered canyons on the warmest, driest and most unapproachable slopes. It is mainly confined to the foothills and valleys near the coast. It is easily domesticated as far north as San Francisco, and with us is quite a hardy shrub, requiring only a sheltered position to protect the flowers.

A rich sandy loam soil is most suitable. The species may be increased by seeds, sown in spring, but only the most careful and painstaking are usually successful. The seeds do not germinate for four to eight months or longer. With care the roots may be readily transplanted. Cuttings may also be made to grow. Single plants do not seem to mature seed in cultivation, but when grouped, as in the wild state, the seed mature abundantly. The stems multiply rapidly from the roots, until a single plant will occupy a considerable area.

W. Goldring, writing from London (*Garden and Forest*, i. 291), says of the *Romneya*:

I have just seen this glorious flower in Kew gardens. With us it is one of the rarest and choicest border flowers we have. One need not be an enthusiast to admire its great satiny blossoms of snowy whiteness and adorned in the middle with a tuft of stamens like a golden tassel. It has the reputation of being a "miffy" plant—that is, it wants much attention and then often does not reward us by behaving well.

There is now a considerable home demand for this handsome shrub, and for California homes there is no plant more desirable for the lawn or garden. As a pot plant in the East and Europe, it is eminently a success. It blossoms when small profusely, and while the flowers are not nearly so large as they can be grown with us, yet it well repays all the labor and care bestowed upon it. No picture can do this magnificent flower full justice. The waxy, delicate texture of the petals the pencil fails to reproduce as well as the airy grace of the plant itself. We wish we could place the reader before such a field of them as we have seen in the canyons of Lower California, where, climbing far up the mountain-sides, away from the reach of any but the most enthusiastic botanist, their numerous large white flowers show off, with startling beauty in the morning sunlight. It seems a pity so many should thus waste their sweetness so far from appreciative eyes, but the bright-winged butterfly harbors no kindred thought as he flits from flower to flower.

In the designation of a State flower by our State Floral Society, the choice lay between two so-called "poppies"—the *Romneya Coulteri* and the *Eschscholtzia Californica*—the latter winning not upon beauty but upon its greater elements of popularity.

The Leading Industry.

Last week a contemporary gravely asserted that it was humming to think that Utah had in great part to depend upon mining for its prosperity, and cited the fact that notwithstanding Nevada mines had yielded largely, no particular benefit had accrued to that State. And when we tried to answer that about all the prosperity of this Territory really was due to mining, that it was that great business which kept the arteries of trade in the Territory bounding with life; this contemporary came back and inhaled on its first proposition, and carried the idea that a town like Provo as compared with a town like Park City was a certain evidence that the Territory relied more on other things than on mining. Thinking that perhaps an object lesson would be better than anything else to show the truth to a contemporary so perverse as is ours, we applied to the Ontario Company for the figures of last year,

and Mr. Thomas Almy kindly gave us the subjoined:

OUTPUT ONTARIO SILVER MINING CO. YEAR 1890.

Ore sales.	Tons ore.	Fine oz. silver.	Sold for.
Bullion.....	12,038	812,750.02	\$ 765,318.93
.....	23,692	984,200.71	1,086,765.47
Total.....	35,985	1,796,950.73	\$1,742,084.40
Dividends, 1890, 12 of \$75,000 each.....			\$ 900,000.00
Disbursements, 1890 (dividends not included).....			1,117,055.06
Disbursements directly in Utah, viz.:			
Pay roll and salaries.....			\$ 635,000.00
Cord wood.....			84,180.75
Lumber and timber.....			35,649.60
Coal (from Coalville).....			81,704.22
Salt.....			29,662.82
Castings (Salt Lake foundries).....			12,807.10
Beef and vegetables (no groceries).....			21,724.03
Hauling and sampling ore.....			55,853.10
Total.....			\$ 806,731.52

Many other supplies, such as powder, oil, candles,

we believe one-half, or close to one half, was invested right here. The theme might be elaborated upon to any extent, but the foregoing is sufficient to show that our contemporary sometimes does talk as do the foolish talk.—*Salt Lake Tribune*

Forests and Floods.

Ten years ago I wrote a pamphlet setting forth the fact that considerable areas of brush and timber in the foothills and mountains were being burned off every year and the brush on some small portions of such burned districts was being dug out by the roots. The result of undue forest or brush destruction was shown to have been in other countries an increased flood flow and torrent action on the one hand, and on the other a diminished supply of permanent perennial water in either wells,

fires and the consequent increased detritus delivered by the mesa and mountain streams. Flood water thus charged with sand, stones and howlers has an erosive power similar to air charged with sand and used as a sand blast. It is for this reason that we see barrancas, gullies and washouts where we formerly had none. No farm in a bottom land near any stream is now safe. This is true not only from the increased cutting power of the streams, but also because the capacity of water to carry detritus depends on the gradient of the water flow. After fires or other denudation the streams usually come out of the steep mountain grades charged to their full carrying capacity with detritus. As soon as the lower grades are reached some of the load must be dropped. Such deposits fill up the stream bed and there must be a continuous tendency in such streams to break into new and unexpected courses and to do great ruin.

Our remedy is a forest policy such as necessarily has forced upon all civilized countries but ours. Riparian timber should indeed be cut, the forests should indeed supply us with firewood, but the forest can and does in other countries provide man's wants without any necessity of forest destruction. As for the fires that every year heat the hot autumn, superdry the air already overdry and mar and waste our mountains, they are inexcusable on any ground. They are sometimes caused by negligence, but the great majority are purposely set. One hundred and fourteen fires started in separate and distinct places in the mountains and foothills of the Santa Monica range last year between the Rodeo ranch and the Malibu. Some of these burned only a little way, others extended over miles of territory. One of them nearly burned up the pavilion at the forestry station, and did burn large quantities of the trees planted on the forestry ground. Fires are the forerunners of floods. Every year our arroyos and torrents widen their beds; every year some stream changes its course; every year the damage by flood of a given rainfall increases. And this is only the commencement. Many countries have been ruined by forest denudation unchecked, and civilized countries have come to an appreciation of the facts, and have after an expensive schooling taken their precautions in a national forest policy. To indicate what the cost of these forest lessons is, we may cite the valley of the river Durance in France. This stream rises in a mountainous country originally forested. The trees were cut and rafted out, sheep were introduced, the brush burned, and the mountains quite denuded. The result was the cutting away by floods or the covering up by torrent detritus of 200,000 acres of fine lands in this single valley.

We must all join together and stop this wasteful and dangerous destruction of the coverings of our mountains.

Large numbers of trees have been planted in Southern California, but these are all in the valleys, and while helping the climate cannot control the flood-waters coming from the denuded mountains. These must be controlled in the mountains and foothills.

Levee districts are an expensive palliative for the results of forest fires. There never can be a remedy. The difficulty of holding an effective levee can be seen on the Los Angeles river, where great expense has been gone to by the railroad companies. Their levees are costly, unreliable, and made of material certain to rot out under ground. Besides the great first expense of any effective levee system to care for mountain streams, there is a still greater expense in the necessity of raising the levee banks from time to time. This necessity grows out of the inability of torrents to carry on the valley grades what they pick up in the mountain grades. Consequently the torrent beds rise above the general level and no levee can make them secure. So it may be observed that the outlet from the mountains of so many of our torrents is on a talus or deposit of sand, stones, etc., higher than the surrounding country, and this must become more and more the case as mountain denudation increases.

I have seen levees to hold torrents on the Italian side of the Alp valleys, 78 feet high and then only 18 feet above the bottom of the torrent bed. This taller torrent is consequently at its bottom 60 feet above the surrounding country. I have stood on this levee and looked down on the top of four-story houses in the city of Bozen.

I suppose that it is impossible for the people to realize what a mountain torrent in a country like ours will do. I suppose that it is impossible for them to realize that the true and only reliable remedy is in the mountains and not in the plains, is in the brush and forests, and not in levees. Premising that we can only hope for palliation at present, it may be well to suggest that one of the best flood and torrent breaks in this country, where water is permanently near the surface, as in all the river country below Los Angeles, is the willow hedge. The willow brush should be cut from five feet long, and set about 2½ to three feet below the surface of the stream, and close to and under the bank to be protected. It must then be wired together thoroughly. In case the exposure is great to strong currents, a scantling or good post should be driven in deep, every ten feet, to anchor the wires. The next season this will form a living levee that no flood will move. No insects injurious to fruit trees harbor in willows. I speak from experience, having in a mountain district as road overseer taken this measure of protection, and never lost a culvert, grade, canyon road, nor bridge.—*Abbot Kinney, in L. A. Express.*

OUR GRANDEST WILD FLOWER—*Romneya Coulteri*.

ROMNEYA COULTERI—REDUCED FROM LONDON "GARDEN."

machinery and groceries, were purchased of Utah merchants.

He adds a note in which he says that the disbursements in cash per month from the Salt Lake offices are \$80,000; 80 per cent of this is paid out at Park City, 18 per cent at Salt Lake City, and two per cent in foreign remittances. It will be seen that the receipts of the mine last year amounted to \$1,742,084.40. The mine paid in dividends \$900,000. The disbursements amounted to \$1,117,055.06, and in Utah for salaries, the pay roll, cord wood, lumber and timber, coal, castings, food, etc., the disbursement amounted to \$806,731.52.

Probably this is as prosperous a mine as there is in Utah. There are but four other mines in Utah that compare with it, and yet we see that half the product must be given up for labor and supplies, and this was paid out in Utah. With most of mines the expenses as compared with the profits are two or three to one. Of the amount paid out in dividends by the Ontario last year, one-quarter at least, and

springs or rivers. In a mountainous, and especially in a dry mountainous country, these results were shown to be prompter and greater than elsewhere.

The warning was then given that unless some check was put upon the denudation by fire of our watersheds, very serious consequences would be likely to ensue. Ten years have passed and ten fires and waste have gone on. Is it not now possible from our experience to say that in proportion as a mountain watershed is denuded so much the greater will be the flood flow for every inch of rainfall?

As the watersheds are denuded, the water flowing from them carries more and more sand, stones and soil. This detritus is added to the volume of the water. From my own measurement I believe that one-third of the volume of our torrents in floods is often composed of detritus. Of course this adds greatly to their erosive power, not only as to volume but as to erosive or cutting capacity. This feature of our torrents owes its great recent increase to mountain

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Alpine.

A LOOKED-FOR REVIVAL.—Genoa *Courier*, March 21: It is reported that an English company has taken hold of the Colorado No. 2 in Alpine county and that \$10,000 is to be put up within 60 days for the purpose of opening the tunnel and making other preliminary arrangements for commencing regular work. It is further stated that the company must put up \$240,000 by the 1st of next July or forfeit their right to the property. Just how much importance is to be attached to this statement we are unable to say, but some of the residents of Alpine confidently look for a revival of the mining interests. Dan Coffin recently sent on and had the Good Hope claim, situated a few miles above Markleeville, relocated and expects to snout put a few men to work. The claim is situated within sight of the stage road. There is a good millsite where the ore, which is free milling, can be run from the mine to the mill in a chute. This mine was abandoned some years ago and the last ore taken out worked \$6.25 to the ton and it is now believed that it can be made to work \$11 a ton. D. Bari was working the old Leviathan copper claim above Monitor, but suspended work during the storm. The ore is very rich. This mine was worked years ago.

Amador.

MILL MOVED.—Amador *Dispatch*, March 21: The old Hardenburg mill has been removed from its former site near the bank of the Mokelumne river at Middle Bar, and will be replaced near the working shaft of the mine, where large quantities of good-looking ore are being taken out. It is thought that the mill will be ready for operation in about a month.

PLYMOUTH CON.—Amador *Ledger*, March 21: This company's eastern office is in receipt of the following news from the mine: The upraise is 35 feet above the tunnel. The vein is two feet wide and carrying high-grade ore.

BELMONT.—The superintendent of this mine reports the surface tunnel has been extended 25 feet the last week. Mill is running daytime on ore from face of tunnel; 30 feet yet remains to be driven to where the vein is said to be 20 feet wide, which will enable the company to keep their 10-stamp mill supplied full time.

MISCELLANEOUS.—The water has been taken out of the Bell Wether claim, and two shifts are employed in sinking operations. The one-stamp mill of the Amador gold mine was employed last week in a test crushing of the cement and gravel left by the placer operations on Red hill in early days. We are unable to say how it turned out.

SUTTER CREEK.—The laying of pipe for the Maboney mine has commenced. The ditch for the pipe is almost finished, and inside of three weeks they will in all probability have all connections with the mill-and ditch made, when crushing on surface ore will be commenced. A bridge is to be built across Sutter creek to carry the pipe. It will be in close proximity to the bridge of the Amador canal and very similar in construction, although not so heavy. It will cost in the neighborhood of \$400. The mill is being put in thorough repair, and will be in readiness to commence operations as soon as the other work is completed. The Lincoln mine, after a short rest, is running again with good prospects of a steady run.

Calaveras.

ENCOURAGING PROSPECTS.—*Mountain Echo*, March 19: There is being considerable work done on the pocket vein belonging to Thos. Hardy & Co., situated near the Marble springs, near this town. Several hundred dollars were taken from one pocket one day last week, and flattering prospects have been made all along the vein. The gold found in this vein is said to be the heaviest and finest of any found in this locality. That there is a large deposit of gold somewhere along the vein there seems to be little doubt, as indications point strongly that way.

UTICA SHAFT.—A contract is let to sink the south shaft at the Utica mine in this town 230 feet deeper, which will make the total depth when completed, 800 feet. This shaft will tap the vein deeper than any shaft ever sunk in this locality.

El Dorado.

NEW MILL.—*Mountain Democrat*, March 21: Doc Pratt's mining ventures have turned out so well that during the past week he has had a new mill constructed for his claim, and soon the sounds of the big whistle on the hoisting works will announce the beginning of business therein.

Inyo.

RICH FLOAT.—*Register*, March 19: Scott Broder is coming over the toll road between Deep Springs and Big Pine a few days ago, picked up a piece of rock that attracted his attention. On breaking it open it was found to be peppered all through with gold—enough to give an assay value per ton running way up into the thousands. The piece shown the *Register* was the richest specimen we have ever seen in the county, not excepting the Keynot of years ago. The prevailing rock in the neighborhood of where the chunk was picked up is slate. The ledge from which this float came has not been found as yet.

Nevada.

A LIVE DISTRICT.—*Transcript*, March 24: There are estimated to be about 400 men mining for quartz at Maybert and Ormonde, Washington township, and in the vicinity of those places. The Yuba mine has 75 men and runs 25 stamps with good results. The Eagle Bird has 100 men and 30 stamps are pounding out gold. The Washington works 40 men and 20 stamps are pounding away at a nice profit. There is between \$10,000 and \$12,000 disbursed monthly for wages. Much prospecting is going on all through that section. Fritz Meister is getting ready to start up work on the rich ledge in litigation between him and Capt. Donahue. At the Bluebell the ledge, lost some time ago, has been rediscovered and looks splendid. On Canyon creek the White Brothers are running a tunnel to open a promising deposit of ore. John Lynne is getting ready to begin work at his claim on the ridge above Canyon creek.

THE ST. JOHN MINE.—*Grass Valley Union*, March 25: The ledge in the St. John mine now

shows a width of six feet of gold quartz, and it all looks like good milling ore. But little of the quartz has been taken out as yet, the work being mostly confined to the stripping of the ledge, but occasionally crosscuts are made to determine the quality of the quartz. It shows well in mineral and prospects in free gold.

Placer.

AS RICH AS EVER.—*Placer Herald*, March 21: We received a pleasant call last Saturday from Mr. A. Breece, late of Bath in this county, now a resident of S. F. Mr. Breece and Judson Wheeler are the owners of the Paragon drift mine at Bath, and while the Paragon has been a liberal dividend payer for many years, the present prospects of the mine are as encouraging for the future as at any time in its history. In working their old channel, the main direction of which has been a little west of north, they have cut into a new channel, coming in from the east toward the Hazard claim in Volcano canyon, which is extensive and rich. They own 5000 feet on this new channel which so far as prospected is from 200 to 300 feet wide; the gravel on an average pays \$6 to the car and can be taken out at the rate of two cars a day to the man. Contemplate a bed of gravel 5,000 feet long, say 250 feet wide, six or eight feet deep, which contains for its owners from \$3 to \$5 of net profit for every miner's car load, then you can form some conception of the richness and extent of the famous Paragon drift mine in Placer county.

THE GRAY EAGLE.—We received a call last Wednesday from W. F. Eicke, foreman of the Gray Eagle drift mine, located on the ridge about five miles this side of Forest Hill. So far, work on this mine has been mainly in the way of prospecting the property, but the prospecting has now sufficiently advanced to render certain the existence of a rich and extensive channel which promises soon to yield big returns to the lucky owners. In the main tunnel at 253 feet from the mouth they ran into the channel. For 200 feet the tunnel has been continued through the gravel, and yet the channel has not been crossed. The gravel above the tunnel followed back on the rim is very rich, and at 1700 feet from the mouth of the main tunnel an upraise has been made which at about 140 feet is expected to cut through to the gravel, and which, Mr. Eicke thinks, will probably be finished by the time he gets back. The gravel from the higher rim or upper channel will be worked through this upraise, while the gravel in the main channel below the level of the main tunnel will be worked through the said main tunnel, the mine being kept dry by pumps put in for that purpose. Considerable gravel has already been taken out, but so far none to speak of has been washed. Everywhere it prospects rich and it is known to be extensive, and the company feel fully assured now that they have a big and rich mine.

THE ECLIPSE MINE TROUBLES.—*Nevada Transcript*, March 20: The trouble about the Eclipse mine of Placer county, which was partly owned and wholly managed by J. B. Patterson, once an Assemblyman from this county, is not yet ended. The latest is another attachment levied by J. G. Fredenburr, a well-known citizen of this county, who kept the boarding-house while the mine was running. This attachment is upon the personal property of the company for over \$500 for board furnished the men and a few other smaller claims which make the total \$577.40. Schaw, Ingram & Batcher, a Sacramento firm, are putting into force an execution on a judgment obtained in Sacramento county for \$683.47. This amount is for merchandise sold to the Eclipse Mining Co.

San Diego.

AROUND JULIAN.—*Sentinel*, March 20: Work is being pushed on the Helvetia and High Peak mines by W. O. Havermale. Cheering reports continue to come in from the Mesa Grande mines, notwithstanding the stubborn litigation in progress. There is considerable activity now going on in the mines along the line of the new grade between Julian and Banner. The first we notice in passing down the road is Messrs. Garrison, Burke and Murphy who have a lease on a portion of the Gardner mine and are getting things in shape for a profitable summer's work. The west half of the Warlock mine has been leased by Holland & Co., four hardy miners who have taken hold in earnest as though they mean business. The east half of said mine has been leased by William & Co., who have flattering prospects for the coming summer. The Warlock has long been considered one of the best properties in camp. The vein is not large, but rich, milling from \$60 to \$100 per ton. We are glad to see the miners taking hold of ground on their own account. The camp would be better off to-day if more of that kind of work had been done in the past. The most important strike made in camp of late is reported at the Antelope and was made by Charles Dwyer, foreman of the San Diego & Warlock Mining Co. Dwyer is a very quiet man and says but little, but all who know him say he is an A. 1 miner. He has—we are informed—leased from the superintendent, John I. Minear, that portion of the ground on which the rich ore was uncovered. This strike in the Antelope is no surprise as it is a well-known fact that the Antelope has turned out some of the richest ore ever mined in the camp. The Blue Hill tunnel—from which grand results are expected by all who are familiar with the locality—is now into the mountain 500 feet. The present contract calls for 1000 feet. Work is well under way at the Fraction and Cable mines. A crushing of ore has just been put through the new mill of the Gold King & Queen Co., at Banner, with satisfactory results. Rich ore from the Cincinnati Belle mine is now being milled at the company's mill. The Ready Relief mine, as usual, is turning out fine ore, but nothing else is ever expected of it. Work at the King and Queen is being carried on in an extensive manner by Supt. Wilkins. The company has a complete plant and is making good use of the same. The Stonewall mine, which has been reported played out just 947 times in the last 20 years, still manages to keep the 20 new stamps running night and day and is doing far better than her traducers. In fact the mine is showing up splendid ore in the lower levels and those who have had their pencils sharpened for the last three months to write her obituary had as well look for other employment. The Wilcox mine is being developed and is a promising piece of property. Rumors are afloat to the effect that the Owens will resume operations the first of April. Charley Minear's 8-horse team has arrived with the remainder of Kerr's new mill

and it will soon be in operation; then miners can get their rock worked in any quantity from half a ton up and at a cheap rate, which will give the miner more independence than he could ever before assert in the district. Considerable prospecting is being done and a disposition seems to prevail among the miners to lease and work property for themselves, which we look upon as the best indication of permanent prosperity in the camp. The outlook is indeed encouraging.

San Bernardino.

GAVILAN GOLD.—*Cor. Bulletin*, March 24: The Gavilan gold mines are situated ten miles from Cajalco, in the southeastern portion of the San Jacinto estate. Here the work of development is in charge of James H. Crossman, acting superintendent, under General Manager Colonel E. N. Robinson, and is slowly progressing. These mines are believed to be meritorious, but Colonel Robinson seems to think one thing at a time is a good rule to follow. When the tin mines are fully developed and on a paying basis, he probably will pay more attention to the Gavilan gold mines and their yellow product.

TIN FROM SAN JACINTO.—*Cor. Chronicle*, March 25: The small mill and oil furnace of the San Jacinto estate continues to run in a very satisfactory manner. The running off and capping of the oil furnace to-day under the supervision of Stephen Harris, the expert from Cornwall, was of a very satisfactory character. Hundred-pound bars of tin are being cast at the present time. The furnace will continue to run until it reduces all the black tin accumulated on the smelting-furnace floors. The result from the present smelting will be forwarded to San Francisco to illustrate and prove that tin can be produced in quantities and quality to meet the demand of the American market. The general manager, Col. E. N. Robinson, intends to make an exhibit before the Board of Trade in San Francisco.

Sierra.

SIERRA CITY.—*Cor. Mountain Messenger*, March 21: Sam Lock returned from below last week, and started work in the Chips' mine, stopped for some time by snow filling up the ditch. Work has again commenced at the Wm. Tell ledge, where five men are working. There can be but little doubt that this will prove to be valuable property, and the owners are going about the work in a business like way. With a little mill the mine has thus far paid expenses. The owners walk to the mine—no buggies—no livery bills to pay, and I think the future of Sierra City depends a good deal on this mine, although there are several others that will be worked this summer. The Butte Saddle, they say, is looking well. The men working there say they have a fine ledge. There are a great many idle men here, waiting I suppose, for the Mountain mine to start. From present appearances, the sawmills will have plenty of work this summer.

UNTRUE.—The report that a 50 ounce piece of gold had been found in the Ruby mine proves to have been untrue. A few weeks since a three or four ounce piece was found, and this has grown to 50 ounces.

EXTENSION.—The Bald Mountain Extension Co. made 32 feet with their main tunnel and 25 feet with their upraise, last week.

Siskiyou.

BLUE GRAVEL.—*Yreka Journal*, March 20: Lee, Lash & Co. have been taking out a great amount of blue gravel from their extensive claim at Greenhorn during the past week. The gravel is exceedingly hard on account of being packed so tight at bed rock, but crumbles easily after being exposed to the air for some time on the surface. The company works day and night shifts of eight men to each shift, comprising four men in the drift all the time. They are breasting up and down the creek, the channel taking an eastward course toward the Killdore hills in Shasta valley and across the southern tributary of Yreka creek on the east side of the Scott Valley road. The gravel taken out at present pays about an ounce a day to the pick, or two ounces each 24 hours to a drifter, and will probably average that amount, more or less, until the entire dam is worked out, which is likely to last several years. Some of the gravel taken out is so hard that it will not dissolve in water, and is laid aside for air slacking before washing. A blower will probably be put in the mine soon to force fresh air into the drifts for more comfortable work, besides digging another shaft when the drift is extended about 200 feet or more from the first or present pumping and hoisting shaft. Several new companies from Montague, Yreka and Shasta valley are prospecting in the Killdore hills, some three or four miles south of Yreka, with a firm belief that the blue-gravel channel can be found all the way from the vicinity of Yreka basin and Shasta valley to a connection with the blue-gravel beds of the Cottonwood creek locality near Henley and Hornbrook. Several shafts and wells sunk between Yreka and Montague show rich deposits of blue gravel, where the channel may prove very extensive. The blue-gravel leads on the east side of Yreka creek are all under the sandstone formation, and can be traced along the old Oregon stage road to Siskiyou mountain.

WINDGAMS.—The Klamath river miners are all busy in commencing work on windgams or making preparations to do so, by getting timber and lumber on the ground. Several companies are putting in cribs above Oak Bar on the lower Klamath, and similar work is in progress at Honolulu and above, on the upper Klamath. The Chinese companies all along the river, from Hamburg Bar to Hornbrook, are also reopening their claims by putting in windgams, and the prospects indicate more extensive mining operations on the Klamath during the coming summer than ever before known, with the certainty of realizing a larger amount of gold-dust than for a number of years past. The heavy freshets of last winter, while doing great damage to river claims, cleared out immense piles of accumulated tailings and boulders in the way, so that the stream is now in good condition for successful operations on a large scale. The directors of the Yreka Blue Gravel M. Co. are negotiating for a diamond drill, for the purpose of boring to find the locality and extent of blue-gravel deposits in this vicinity. Parties who have been exploring the country between Henley and this place, and out toward Staveout, Killdore hills, Cram's gulch and Orr's, believe that an inland sea or river existed in prehistoric ages to the extent of six or seven miles in width. Work will soon be commenced on the extensive cinnamon ledges in the Siskiyou foothills, on the west fork of Beaver creek, under the management of Mr. McGee, who is only

waiting for favorable weather to start operations. **S. H. MINE.**—*Cor. Siskiyou Telegram*, March 21: The S. H. mine started up two weeks ago with a fairly good head of water, which has increased slowly until at present we have a full head. Everything is running smoothly and the earth and boulders are being mopped into the flumes as fast as it is possible for 2000 inches of water to do it. The Low Hill quartz mine has suspended operations indefinitely, Mr. Eastman, the superintendent, having gone to Eureka to procure concentrators that he may be able to work the sulphates. Mr. Henry Murray of Callahan's Ranch, one of the last year's pipers, has returned and is plying the water to the bank very satisfactorily.

Trinity.

BUCK'S RANCH MINE.—*Journal*, March 21: W. J. Grigsby was in town Thursday on his way to San Francisco and informed us that the Buck's Ranch mine, in which he is interested, is doing very well. A recent crushing went between \$10 and \$11 per ton. This kind of ore will net the company about \$7 per ton, according to Mr. Grigsby's account of working expenses.

Tuolumne.

SHUT DOWN.—*Tuolumne Independent*, March 21: The Hesleg mine, at Quartz mountain, has been shut down for good, and will be gutted of its machinery. The closing down of this mine will have a somewhat depressing effect on the mountain, as it furnished considerable labor. We are informed that Mr. Wm. Phillips, who has for many years been foreman of the mine, wanted to lease the property, but the company refused. The Knox & Boyle mill, now owned by Mrs. A. B. Preston, will be refitted and repaired to do custom crushing.

NEVADA

Washoe District.

CON. CAL. & VA.—*Virginia Chronicle* March 21: 1200 level: Continue to extract some milling ore from above the line of the drift run north from the east crosscut No. 1 from the south drift from the shaft station. 1300 level: Have continued to extract some milling ore from the point where the upraise carried up from the end of the east crosscut from the south drift connected with the 4th floor stopes. 1500: The width and quality of the ore which is exposed in the opening 43 feet above the sill floor of this level continues to hold good. 1600: Have continued to take out some ore along and above the line of the drift run east through the old stopes on the sill floor of this level; also from the stopes which are being worked both north and south from that drift. Have continued to stoop out ore at the point which is 200 feet south from the north line of the California ground and 44 feet above the sill floor of this level, and the ore there continues to be of good quality. 1650 level: The usual quantity of ore has been extracted from the various openings of this level; also some ore in working out from the winze No. 2, 35 feet above the sill floor of the 1750 level. Have extracted from all parts of the mine during the week 1537 tons of ore which was shipped to the Eureka mill. The average assay value of all the ore worked at that mill during the week (1520 tons) was \$31.90 per ton. Bullion shipped to Carson mint, assay value, \$28,771.06.

OPHIR.—The east crosscut started from near the end of the drift run north from the drift run west from the winze, 122 feet below the sill floor of the 1300 level, has been extended 21 feet; total length, 56 feet; continuing in a porphyry formation, which shows low assay value.

UNION CON.—East crosscut No. 2 on the 1465 level, started from the north lateral drift at a point 200 feet south from the south boundary line of the mine, has been extended 31 feet; total length 721 feet, continuing in a soft porphyry formation showing clay separations.

MEXICAN.—The east crosscut No. 1 started from the main north lateral drift at a point opposite the west crosscut No. 1, has been extended 25 feet; total length 565 feet; in a harder porphyry formation.

GOULD & CURRY.—800 level: Have extracted from old stopes during the week 60 cars of ore of fair quality. Winze No. 1 has been sunk 10 feet through quartz and porphyry; total, 25 feet.

BEST & BELCHER.—800 level: West crosscut No. 1 has been extended 12 feet; total 184 feet; face in hard quartz. East crosscut No. 1 has been extended 20 feet through porphyry, clay and stringers of quartz; total length, 52 feet.

ANDES.—The east drift from the main north drift on the 420 level was advanced 24 feet, connecting with the winze from the 350 level. Have been cutting a drain in the main north drift. The east crosscut from the south drift on the 420 level was advanced 20 feet. No material change in the formation.

YELLOW JACKET.—Shipping 40 tons of ore daily, the battery assays of which average \$18 a ton. Doing some prospecting work in the mine.

JUSTICE.—The north drift on the 822 level was advanced 28 feet since last report and is now out a total distance of 443 feet. The face is in a mixture of clay and porphyry with stringers of quartz through it.

CHALLENGE AND CONFIDENCE.—The joint Confidence and Challenge west crosscut from the north drift on the 300 level is out 25 feet. The face shows quartz having no value. The joint raise from the 750 level is up 190 feet. The top shows quartz having no value.

CON. IMPERIAL.—Work is still being confined to following up and taking out small streaks of ore on the upper levels and overhauling the old stopes.

KENTUCK CON.—Have advanced the raise in the east ledge on the 100 level 8 feet and connected with the 950 level. Have been engaged in timbering the east crosscut from the end of the north lateral drift, and have also saved a small amount of pay ore.

CROWN POINT.—Have started a south drift on the 300 level, which is now out 21 feet. The face is in clay, with streaks of quartz through it. The west crosscut on the 500 level is out 164 feet. The face is in porphyry, clay and quartz. Have stopped work in the 1300 station.

BELCHER.—The south drift from No. 3 east crosscut, 200 level, has been advanced 33 feet; face in a mixture of porphyry and quartz. No. 3 west crosscut, 300 level, has been advanced 33 feet. The face is in porphyry, clay and low-grade quartz. Have stopped the work on the 1400 east crosscut, and are now engaged in cleaning on the 1500 drift.

SEG. BELCHER.—On the 600 level the east cross-

cut from the south lateral drift has been advanced 31 feet since last report, and is now out a total of 176 feet. The face is in clay and porphyry.

HALE & NORCROSS.—On the 1100 level 30 feet back from the face of the east crosscut on our north boundary we have started north and south prospecting drifts following the same low-grade ore that the east crosscut passed through. On the 1400 level the main north lateral drift from the station was advanced a total distance of 275 feet, at which point it connected with the south drift from the bottom of the Savage 1300 level winze. The main south drift on this level has reached our south boundary, and we have started east and west crosscuts therefrom jointly with the Chollar. No. 4 west crosscut near our south boundary on this level was advanced 30 feet; total, 90. This crosscut continues in quartz carrying bunches of ore.

SAVAGE.—Milled the past week 530 tons of ore worth \$17.50 a ton as per battery assays. The north upraise, 300 level, is advanced 31 feet and continues in low-grade ore. From the east crosscut, 900 level, we are stopping ore of fair quality, and are also stopping ore from the east crosscut, 800 level, near our north boundary.

CHOLLAR.—Winze 80 feet south of north line 750 level, is down 112 feet; the bottom is in porphyry. The west crosscut on the north line, 1400 level, is out 30 feet; face in quartz showing low assays. Extracted and sent to the mill the past week 535 tons of ore worth \$15.90 a ton as per battery assays.

POTOSI.—On the 930 level the east crosscut from the winze is out 222 feet; face in porphyry. The winze is down 124 feet below the 1300 level; the bottom is in porphyry with streaks of quartz. The east crosscut from winze, 1300 level, is out from footwall 119 feet; face in porphyry.

ALPHA.—The winze 80 feet north of shaft, 500 level, is down 44 feet; the bottom is in quartz yielding low assays. The north drift from the east crosscut, 180 feet east of shaft, 600 level, is out 46 feet; face in quartz yielding low assays.

UTAH.—On the 725 level the northwest lateral drift for 150 feet from the northwest crosscut No. 2 west crosscut No. 3 advanced 45 feet; face in porphyry and clay. In main west drift, at a point 140 feet from the shaft station have started a drift running in a southerly course to prospect the ground. Face shows quartz assaying low in the precious metals.

OCCIDENTAL.—The stopes on the 400 level are yielding some high grade ore. The south drift from No. 3 upraise below the 400 level is in 50 feet; and is showing fair-grade ore. The south drift from the north line, 650 level, is in 135 feet, and is still in low-grade quartz. The north drift from the winze on the 650 level is in 227 feet and is showing low-grade ore.

Columbus District.

A BRIGHT OUTLOOK.—Inyo Independent, March 20: Candelaria still continues to be a thrifty mining camp. The monthly pay-roll amounts to \$60,000. There is sufficient ore in sight in the Mt. Diablo to supply the milling capacity for a long time. There is a large force of men constantly employed at the Holmes. An English Co. erected a leaching plant last fall and is working the old dumps so profitably that it is expected the work will be considerably increased this spring. A new pipe line will also be laid, the present line being inadequate to supply the demand. The water is carried a distance of 28 miles. Captain Channell, Supt. of the Princess, states that his company is prospecting and opening up new ground but not taking out any ore at present. The future of the Candelaria is very bright, a fact of much interest to the people of this valley, as most of our produce can be marketed there.

Taylor District.

MONITOR.—White Pine News, March 21: Wm. Reed, Supt. of the Monitor mine in Taylor, was in town Thursday after men to fill positions in the Monitor mill which will be started up on the 1st of April.

Highland District.

MENDHA.—Pioche Record, March 19: The Mendha mine at Highland continues steadily to improve, ore being constantly found in the most unexpected places, leading to the belief that it is more than a chimney and that a well defined ledge will be found. The new working shaft is now down some 380 feet, and 20 feet more will tap the lower workings and ore chambers.

Pioche District.

FURNACE TALK.—Pioche Record, March 19: The furnace ran down last Friday, the coal on hand being entirely consumed, and it is considered as doubtful if it is ever run again on its present site. Everything around it is being cleaned up. It is reported now that work on the new furnace site north of town will soon begin, to which the present stack will be removed and a second one added. This was the plan proposed last December, and which the eastern management have since had under consideration. If work is begun at once and pushed, it will be three or four months before the new furnace will be ready to start, but with two stacks in successful operation, we will have a lively town whether the railroad builds in or not.

DAY.—Since reporting on the Day mine several weeks ago, development work there has been steadily pushed and with good results. The strike made in December last, and known as the rich body, is now opened up 135 feet in length and 120 feet in height, with no limits encountered yet. The upper south face of the body assays 330 ounces in silver to the ton, and the lower north face 40 ounces. In the new tunnel the low grade material found several weeks ago has gradually improved, and on Tuesday morning it opened up into a six foot face of ore, going 80 ounces in silver to the ton. The ore is apparently the same character as that of the December strike. The new tunnel was run in the hope of tapping at a different point the December strike, which the management think they have now done, and as the two points are 600 feet apart, the tunnel strike is regarded as of great importance. The new air compressor at the Day is about completed. Three new machine drills are on the ground, and it is expected they will be in operation within ten days. Wood and other supplies are on hand in large quantities, and work on the mine will be vigorously pushed.

ONONDAGO.—At the Onondago, adjoining, the main shaft has now attained a depth of 500 feet, where a drift fur the ledge is now in 20 feet, encountering stringers of ore. It is expected the ledge will be reached in a few days, and that it will

show up as well as in the drifts above. A force of from 28 to 30 men is employed at these two mines.

Tuscarora District.

NAVAJO.—Times-Review, March 20: Stopes on the 350-foot level are looking well and are producing some high-grade ore.

NEVADA QUEEN.—North drift on 650-foot level has been extended 25 feet; total, 174 feet. No change in the formation.

BELLE ISLE.—The 350 stopes are without material change. Nine cars of first-class ore and 32 cars of concentrating ore have been extracted. West crosscut from north gangway, 450-foot level, extended 11 feet; the rock in the face is very hard, showing some spar seams with a slight flow of water.

COMMONWEALTH.—Fourth level—West crosscut has been advanced 7 feet in vein matter giving low assays. East crosscut extended 21 feet. Better assays are obtained as the crosscut is advanced; last 5 feet average assay, \$36.90 per ton. Have started a drift north in the ore; will start south drift as soon as north drift is in far enough not to interfere.

NORTH COMMONWEALTH.—First level—Produced 17 tons first class, average \$242 per ton, and 43 carloads second class, average \$24 per ton. Second level—North drift from west crosscut extended 14 feet in low-grade ore with bunches of high-grade mixed through.

NORTH BELLE ISLE.—North drift from Belle Isle 450-foot level extended 18 feet. The quartz has begun to show spots of ruby silver. The 500 stopes are not looking as well as at last report. Nineteen cars of first-class ore and 89 cars of concentrating ore were broken. No. 4 upraise from the 600-foot level has been extended 9 feet and connected with the 500. An intermediate level has been started from the raise, to open up the ore below the 500-foot level.

ARIZONA.

PLACER MINERS.—Journal-Miner, March 21: Placer miners are at work along all the streams and gulches where gold can be found and are meeting with good success. The Dosoris group of mines, three in number—the Dosoris, Buzzard and Raven—have been bonded for \$30,000. They have each produced large quantities of high-grade ore. C. M. Clark, of the Alice Mining Co., is getting his machinery in position at the Silver Belt mine, and expects to start his engine up soon, taking water out of the mine. The dam of the Humboldt hydraulic works, of which D. E. Keating is superintendent, withstood the recent floods without a break.

CINNABAR.—The McNary cinnabar mines, in Copper Basin, are very promising properties, as far as they are opened up. Assays as high as 80 per cent in quicksilver have been obtained from them, while the general average of the assays are higher than the ore which is being successfully worked in California. Should the ore continue equal in quantity and quality as depth is obtained in the properties, they give promise of becoming one of the greatest quicksilver producers in the country. As the Journal-Miner has no personal interest in the properties, it would be sorry to see them disposed of to any but experienced mining men. It will require the expenditure of considerable money to develop the properties and build a plant for the reduction of the ore. The members of ordinary mining companies, that are new in the business, expect to see their claims pay large dividends as soon as \$2000 or \$3000 have been expended. The men who have had experience in mining know by such experience the fallacy of such expectations. They know that it costs money to delve into the earth in search of hidden treasure. They know that machinery for the treatment of ores is very expensive. The experienced mining man is willing to spend money so long as inducements in the shape of good ore are in sight. The other man wants to see the ore converted into money and the money returned to his pocket at once.

COLORADO.

THE LIXIVIATION PLANT.—Aspen Times, March 20: L. G. Hunt, of Leadville, who has charge of the initiatory steps toward the construction of the lixiviation works in this city, has arrived upon the ground and is gathering a force of men to start operations with energy at once. He says that everything has been waiting upon the plans, but they are now completed, and will be no further hindrance in the prosecution of the enterprise. The plans contemplate the erection of a large plant, complete in every detail. There is now already cut and awaiting the workmen 500,000 feet of lumber. With the material in readiness for the flume and buildings it is expected that very rapid progress will be made in pushing operations forward.

CARBONDALE DISCOVERY.—A report of interesting developments at Silver Crown mine on Avalanche creek has been brought to the city by N. C. Scheu of Carbonade. The company has run a tunnel to the distance of 600 feet which passed a four-inch vein of ore. Last week a drift was started in this vein to develop its size and extent. After going only six feet the vein widened to a thickness of from 28 to 24 inches, the greater proportion of which resembles the Bushwacker ore, and would be easily mistaken for that. An assay of samples taken from a narrow streak of the vein is said to have run as high as 1300 ounces.

BRITISH COLUMBIA.

TO BE STARTED UP.—Nelson Miner, March 21: The Kootenay Lake country has within its limits what is believed to be one of the largest lead mines in the world—Hendryx's Blue Bell—as well as one of the richest silver-copper mining propositions in America—Halls' Silver King. The ore from the mines in Hot Springs district are not only rich in native silver, but their average value is above that of any galena camp in the United States. The gold claims near Nelson are not mere prospects, as one of them—Davenport's Poorman—already takes high rank as a bullion producer. Owing to a scarcity of water the 10 stamps in the mill on the last named property were hung up during the winter. The mill, however, will be started up again as soon as there is enough water in Eagle creek to run it, word to that effect being received by the last mail. Between 20 and 30 men will be put at work in the mine.

COPPER PYRITES.—Last June the Queen Victoria, a copper claim situated about 7½ miles west of

Nelson, was bonded to parties said to be officials of the Canadian Pacific road. The amount of the bond was \$50,000. For some reason, the bond was not taken up. This discouraged the owners, and little work was done on the property until late this winter, when Charles Brown, one of the owners, resumed work in the tunnel that was started to prove the width of the ledge. As the tunnel was advanced the ore became less mixed with waste rock, and it is now believed to be in place. Its grade has also improved, and it is said to be fully equal to that of the Anaconda mine at Butte, Montana. It is copper pyrites, the percentage of copper not being large. The immensity of the croppings and the facility with which mining operations can be carried on, to say nothing of the nearness of the railway track, gives the property a value that can only be increased by the employment of capital.

PROSPECTS NEVER BRIGHTER.—Reports from Hot Springs district are that development work is proving the claims and mines of that section to be wonders. The shaft of the United is down 100 feet and in solid ore. The Tenderfoot shaft is down 60 feet, with good ore in its bottom. The drift in the No. 1 is in high-grade carbonate ore. Altogether, the prospects of the camp were never brighter.

IDAHO.

TRADE DOLLAR.—Idaho Avalanche, March 21: The lower drift on the Trade Dollar lode is still being pushed north to the winze sunk from the upper level. About 200 feet still remains to be run, which is being run by contract. The vein at the present face is 12 feet wide, of fine quartz and the walls are smooth and regular. The quartz runs about \$20. When this drift is completed to the winze an immense body of ore will be exposed which will be in fine shape for being cheaply mined. By the time the roads are open the mine will be in shape to keep a big mill running. Work on the face of the upper level has been suspended for want of timbers, but stoping is being done north from the winze toward the face of the drift. The rock taken out is the richest which has ever been found in the mine. The vein is two and a half feet wide, rich rock, with two streaks in it extremely rich. As soon as timbers can be obtained the level will be continued north.

LOWER CALIFORNIA.

ALAMO.—Lower Californian, March 19: You can get an idea of what's going on in the camp by reading this letter. Drifting is continued on the 150-foot level of the Ulises, following the vein discovered a few weeks ago. The Gold Tree is furnishing rich rock yet to the Princess mill. The Indio is still sinking. The San David is being developed. A stringer of the Montezuma was discovered last week which contained very rich rock. The ground was leased to a party of contractors who will develop it. The Montezuma proper will be re-opened by Albright and Howard. The Aurora is working night and day as usual in good ore. The El Paso is down 85 feet and drifting has commenced on the 25-foot level. The mill will be started soon. The Candelaria mine has been re-denounced under the title of Abandonment and will be re-opened, as also the Blanket Ledge between Alamo and Mexican gulch. The Scorpion mine and mill will be running soon.

NEW MEXICO.

ALHAMBRA.—Silver City Enterprise, March 20: John Dodd, brother of Superintendent Dodd, of Alhambra, and Charles Campbell, made a discovery at that camp recently which may prove a formidable rival for the honor of first place in the mines of that camp. The ore is a sulphide and native silver and closely resembles in appearance the high-grade ores from the surface of the big ore chutes on the Alhambra and Black Hawk mines. Uncle Ben Hobson will soon make another shipment of high-grade ore from Hobson No. 2.

MONTANA.

THE HECLA CON.—Mining Journal, March 21: The annual report of the Hecla Con., operating in Beaverhead county, has just been issued. It shows that the total dividends paid by this company from 1881 to 1891 aggregate \$1,560,000, while the total amount of wages paid to miners during the same period was \$1,480,636.66. The gross disbursements for the decade amounted to \$5,073,499.60. Up to date the total amount of ore mined by this company has been 241,161 tons. The cost of mining the ore was \$20.27 per ton during 1890, which is a large increase. This is accounted for by the constantly increased depth of the mine, increased cost of dead-work, retimbering and costs of machinery. The result of the year's work was a total production of \$627,087.57; total expenditure, \$454,369.27, leaving a net profit for the year of \$172,718.30.

MR. DALY TO RESIGN.—Butte Miner, March 19: The vacancy at the Anaconda recently made by the death of Supt. Michael Carroll has not yet been filled and, from what can be learned, is not likely to be until some little business in which the company is interested is settled up. In the meantime work is progressing as usual under the efficient direction of Joseph Laird, superintendent of the Mountain Con., and Paddy Kane, who has long held the position of shift boss at the Anaconda. It is rumored that in the near future Mr. Daly will resign as general manager of the mines and smelters, his health not warranting him in attending to the arduous duties of the position, and that Mr. Carroll's successor will not be named until after a new general manager assumes control.

COMING TO THE FRONT.—The Receiver claim, located southeast of the Clinton company's ground in Horse canyon, is now coming to the front as a producer. Seven feet of ore that will average 275 ounces in silver per ton and a small per cent in copper has just been struck at a depth of 145 feet. So far about 20 tons of this ore have been raised in the surface and the work is still being prosecuted with a crew of six men. The property is under lease and held to E. F. Kinney.

THE NONPAREIL MINE.—The Deer Lodge Mining and Reduction Co. is prosecuting work vigorously with 21 men on its Nonpareil location at Boulder creek. As is well known, this vein is 133 feet wide between walls and is filled with vein matter containing considerable ore. A shaft has been sunk on it 270 feet, where levels are now being run east and west. This development is with a view to un-

covering one of the several strata of ore which are found in the vein, and is very encouraging. On the 140-foot level the drift is being pushed on a stratum of three feet of ore that assays 29½ ounces of silver and 38½ per cent lead. The company will this week begin to ship ore from this working to St. Louis.

OREGON.

WATER SUPPLY.—Jacksonville Times, March 21: There is still a good supply of water and the miners are making the most of it. There is plenty of water at Ennis & Cameron's mine at Galice creek and three giants are busily employed there. A. W. Sturgis of Forest creek made another cleanup last week which netted him many hundred dollars in gold dust. J. T. Breeden of Applegate, who purchased Klesslin Bros.' interests, is now engaged in putting up the large wheel which will furnish power. John Henry has sold his interest in the quartz ledge on Applegate to his partner, S. Messenger. It promises well, several good cleanups having been made by means of an arastra. The Cinnabar mine, operated by J. B. McGee, is being rapidly put in shape for handling the output, a ditch being in course of construction for sluicing and the iron on the ground for the works.

SANTIAM MINES.—Jefferson Review, March 21: The Santiam mines are attracting great attention in Portland. They are destined to become the center of mining operations in the northwest, in fact on the coast, and everything conduces to this end. The rich find in the Bonanza mine is not the only thing that points that way. The ore that has been taken out generally has been of a paying nature. The Albany Co. will push their mine as soon as the snow is off, and it is probable several other companies will put in mills. There are millions there.

UTAH.

SILVER MOON.—Salt Lake Stock Exchange Journal, March 21: A letter from the superintendent of the Tintic M. and M. Co. property, near Silver City, states that the shaft on the Silver Moon is being sunk as rapidly as two shifts of men can work. The shaft is now in good ore, but it is expected that inside of 10 days a big ore body will be exposed, when shipping will begin. A number of shipments have already been made. It is the intention of the company to list the property with the Exchange.

DALY.—Park Record, March 21: Dividend No. 49 of the Daly amounting to \$37,500 was declared yesterday, and is payable in New York, San Francisco and Salt Lake. Total amount of dividends to date \$1,790,500. Sinking was begun on the Crescent shaft this week, and the work will be crowded as fast as possible. No difficulty is experienced in holding the water in check and connection with the Hanauer tunnel is expected to be made without any serious trouble. T. J. Almy came out from the city this week and paid off the employees at the Ontario and Daly mines and mills, and at the tunnel. The needful—to the amount of about \$80,000 is now floating among the business men.

PIONEER RIDGE.—The prospects for active development on the Pioneer Ridge next summer is already having its effect on the future welfare of the camp, and negotiations are now pending for two valuable properties which, if consummated, will be the means of bringing many thousands of dollars to the camp for investment. The winze on the West end is down some 43 feet, and the ore body is gradually growing larger. There is now more than six feet of ore.

PROSPECTIVE.—There is much talk among prospectors of a busy summer, and the outlook at present indicates that more thorough development work will be done than ever before. Every man who owns a prospective mine realizes that he must put it in saleable shape as soon as possible, if he would realize on it. That is the right idea, for very few men will purchase ground that has no developed indications of a mine. Surface croppings and locations go a long way but something tangible must be in sight or it is hard work to make a sale.

WASHINGTON.

COAL AND IRON.—Ellensburg Capital, March 20: Seaton Bros.' Gold Leaf mine is under bond to Seattle parties. The Swauk placer mines will be worked with good result this season and a large amount of gold will be taken out. Water promises to be abundant, and the miners are prepared to make good use of it. New capital having gone into Peshastan district, a large amount of work will be done there this season, and there are some prospects of a new stamp mill being built there. The iron mines south of Ellensburg are opening up well, and the ore, which is very superior, is improving in quality. This ore, combined with the Uncle Sam, makes pig iron that can't be surpassed in the United States. The same quality of coal found in the Canada mine north of Ellensburg, is said to embody the city. This was the opinion of Prof. Clayton, one of the best mining experts and geologists in the country when he was living, and his views have since been confirmed by W. H. Hampton, who succeeded him at Portland. This coal is excellent for coking, and will play an important part in the reduction of iron ore in Kittitas county. Kittitas county, of which Ellensburg is the great heart and center, can show more minerals than any county in the State of Washington. It has gold, silver, copper, lead, iron, coal, asbestos and aluminum in great abundance and has all the fluxes for the successful reduction of metals.

CONCONULLY.—Okanogan Outlook, March 21: Wheeler & Beckmyer are doing development work on the Montana mine on Mineral hill. The Chilson brothers have bonded the Silver Bluff mine, in the Lime belt, to a Seattle mining Co. for \$50,000. The Ruby Hill Mining Co., recently organized at Spokane, will soon begin development operations on Ruby hill. We are reliably informed that the Fourth of July Co. propose to resume development work on the mine about the 1st of April. There is a movement on foot among some of the leading citizens of Conconully to organize a company for the purpose of building and operating a 10-stamp quartz mill. Dennis McDonald, who is working a force of men on the Red Shirt mine, in the Methow, was in town this week. The main tunnel in the mine is now in over 200 feet, has crosscut two ledges and is expected to tap another, the main vein, in a few days. Mr. McDonald is developing the mine for a Montana syndicate.

MECHANICAL PROGRESS

IRON WORKS IN CHINA.—It appears from a number of the *North China Mail* that the Celestial Empire is soon to be in possession of quite an extensive iron and steel works plant. A site has been chosen on the northern slope of the Hanyang Hills, opposite the native city of Hankow, and thus close to the Yangtze, with which, afterward, the works will be connected. As far as ascertained, the factories will be very important indeed, and will comprise, for the present, two large blast furnaces of the Cleveland, England, type, with all their apparatus, appurtenances, and machinery, capable of producing about 100 tons of pig iron daily. There will be also a complete Bessemer plant, including two 5-ton converters, with their anodes, casting-cranes, large blow-lung-engines, etc. The ingot steel made here will be rolled out into flange rails, so that the specifications include necessarily a large rail mill and all machinery and apparatus for the same. It is known, apart from this, that the manufacture of rails for their future railways has been the chief object of the Chinese in designing these iron and steel works [and also, no doubt, of the delay in the introduction of railways into the country]. A small Siemens-Martin plant will complete the steel work. Its object is the casting of soft steel for ship plates, and special metal for the navy's small arms and gun factory. As for the iron department, it will also be a very complete one, including some 20 puddling furnaces and a plate and bar mill, with all indispensable machinery. It is roughly estimated that the works will cover about 40 acres. They will be intersected by railways on which the astonished Chinese will, perhaps, see half-a-dozen locomotives, small and large, travelling in different directions. The whole plant must be entirely delivered in the first month of next year. An important part of the machinery has already been brought up and landed directly out of two ocean-going steamers.

MOLDING SAND—WHAT IT SHOULD BE.—In a recent number of Ferdinand Kohn's "Iron and Steel Manufacture" is given the following valuable information in regard to molding sand, which will be of value to many readers who have often wondered, no doubt, why castings made in different localities from the same iron should differ so much: "The mold has an important function to perform in the process of casting. It must resist the pressure of the liquid metal in every direction, and at the same time give a free escape to the air and gases generated in the mold while being filled and during solidification. It must give to the casting a clean, smooth surface and allow an easy separation from the sand. It must neither act chemically upon the liquid metal, nor be affected by it at the high temperature at which it is brought in contact with the sand. The higher the temperature of the liquid metal, the more difficult it is to comply with these conditions, and the fewer are the substances which can be used for this purpose. . . . The presence of three per cent metallic oxides in molding sand impairs its refractory qualities. Still more undesirable is the presence of lime, one per cent of which will make sand undesirable for good castings. Lime present as a carbonate gives off its carbonic acid gas at the temperature of liquid iron, causing the latter, when in contact with the mold, to form bubbles and air-passages which destroy the smoothness of the surface. If present as caustic, it will vitrify and adhere to the face of the castings. . . . The heat molding sands are those that contain the largest proportion of silica; from one to three per cent magnesia; an entire absence of lime with sufficient alumina to render the sand cohesive and plastic. Sands of the above description are seldom found in a natural state."

WELDING A SPRING.—A correspondent of the *Blacksmith and Wheelwright*, who seems to have had considerable experience, says: "I see a great many different ways of welding springs and have had some experience of my own. The best method that I have been able to find is the one that I will endeavor to explain for the benefit of my brother blacksmiths. When a broken spring comes into the shop to be welded, I always take its exact length, if it is a main leaf; if not, it doesn't make much difference. I then either take the devil's hitch on it or just a common scarf lap. In the meantime, do not heat above a cherry heat. I then punch one or two holes in the ends, rivet them together with Norway iron rivets, as no other kind is as good for welding steel. This done, I heat it red-hot and then put on my horax and let it melt before I put any coals over the steel. I then take a heat on it and take it out and weld it fastways with the first heat. Never strike it on the edge the first time. I now put it in the fire and take my second heat on the spring, then take it out and hit it three or four times fastways, and finish up the edges. By this method a man will hardly, if ever, hurt a weld open, and if he tries to make his weld at one heat he will fail a great many times; whereas if he would take the second heat, he would be all right. My reason for using Norway iron rivets is, as any person using them once will find, that they will weld to steel better than common iron. I have tried a great many different ways, and I find this the best of them all."

THE BARGAIN RAIL, a California invention appears to be attracting considerable attention

among railroad men at the East. This rail, it is claimed, possesses several advantages over the steel rails in common use. These rails will be laid on the belt railroad line of this city. There is a report that a section of the North Western railroad out of Chicago, will be laid with these rails as a test. Shipping rails for San Francisco to Chicago will seem very much like sending coals to Newcastle; but stranger things have happened and may happen again.

JAPANESE SKILL IN METAL WORKING.—The Japanese are past masters in the treatment of alloys both in texture and in color, and no better guides exist. They achieve their grand results by the simplest means—a judicious blending of various metals, including and picking. Copper is the basis of their chief alloys, and by incorporating with it certain proportions of gold and silver they obtain remarkable results in color through the pickling process. But not only do they get striking effects from their alloys and pickling—their mode of working up the metals is a thing to be studied. For instance, they will take six or seven plates of different metals and alloys, weld them together, and then, by drilling, punching up and filling, get a surface in which all the metals show in a manner which is truly wonderful. By the range of tints at their command they can work out on a metal surface scenes of animal life, landscapes, etc., with effects never dreamed of by metal-workers in the Western world. Among some examples recently shown in England was a knife-handle on which was a representation of a duck dipping its head under the water of a stream on which it was swimming, the arrangement of the different alloys by which it was composed and the pickling being so well arranged that the neck of the duck was seen as under the water, when the handle was held in a certain light. Another example was a sword-hilt on which some minnows not more than one-sixteenth of an inch in length, each having a pair of gold eyes, were swimming upon a gray stream, the effect of their being actually below the surface of the water being suggested with marvelous skill. Imitations of wood, grain and marbles were also shown.—*Jewelers' Weekly*

NEW METHOD OF REDUCING STEEL.—It is now claimed that by a new method, plates for steel vessels may be made as strong and elastic as by the open-hearth process, this result being due, in the former case, to the use of small converters, having a capacity of three or four tons. By the open-hearth process the iron is reduced or melted on a platform, the heat coming from the flame which passes over it, the amount of iron melted varying according to the size of the furnace, generally not exceeding 15 or 20 tons. Metals reduced in this way allow of an examination during the heating process, the molten mass being viewed through a piece of blue glass, it being thus easier to obtain better indications as to the length of time required to secure the most satisfactory product. The new process is but little different from the Bessemer, the only distinction being in regard to the size of the converter, a large vessel being used, on which it swings or turns. In the lower edge is a pipe, through which air is forced at sufficient pressure to prevent the metal, when melted, from flowing into it. The converter is hung at an angle, and as it turns, the air forced up, permeates the mass, reducing the metal at a more rapid rate than by any other process known. It disposes of the objection raised against the Bessemer operation, of the air not going thoroughly through the whole mass, and it is also claimed that the product of this improved process is more even than by the open hearth.—*Eng.*

NEW METHODS FROM SWEDEN.—Herr C. A. Caspersen of Margretskil, Sweden, has recently obtained a patent for testing the hardness of iron or steel while in the process of manufacture. His method is to conduct a current of electricity through a test piece of iron or steel, letting it melt the same, upon which the strength of the current necessitated in the operation is compared with the strength of current required for the fusion of a standard piece of metal of a determined degree of hardness and of the same diameter as the piece tested. The hardest piece will resist longest, but melt if the current be maintained sufficiently long. By the aid of an ampere meter, metals of varying hardness may be tabulated so as to furnish a scale of hardness of any metal treated, through the number of amperes required for its fusion. Johann L. Sihenius, also of Sweden, is the patentee of the new method of casting metals under the influence of centrifugal force, by which the particles of metal are brought into a position radial to the axis of rotation as the metal cools, and by which gas bubbles are also removed and any impurities forced into the circumference or outer skin of the casting.

A SERIES OF EXPERIMENTS, made at the Baltimore Copper Works, in the electric smelting of copper, has resulted so favorably that a company has been formed and large works are to be built on the line of the Baltimore and Ohio road in South Baltimore to use the newly-discovered process. An extensive electric generating plant will be put in. The inventors claim that the new process will materially reduce the cost of refining copper.

LIFE OF A LOCOMOTIVE.—The locomotive engine is said to have a maximum life of about 30 years. The annual cost of repairs is from 10 to 15 per cent of its first cost.

SCIENTIFIC PROGRESS.

The Energy of a Blast Furnace.

Few persons, save those connected with the manufacture of pig iron, are aware of the enormous and insatiable appetite of one of the largest blast furnaces. The figures hitherto given failed to convey an adequate idea of the immense quantity of materials that pass through such a furnace, and it is only when the total daily amount of these materials is considered that the tremendous igneous activities constantly at work in that combination of hurricane and volcano—a modern blast furnace of the first class—can be fully appreciated. Such a furnace will have passed through it in 24 hours the following materials:

	Gross tons.
Ore.....	583
Coke.....	442
Limestone.....	158
Atmospheric air (blast).....	1,041

Total.....2,225
Which is equal to 92 tons per hour, or 1.53 tons per minute. From this quantity of materials there will be produced in 24 hours 784,000 pounds, or 350 gross tons, of pig iron, which is at the rate of 32,666 pounds, or 14.57 tons, per hour, or 544 pounds per minute.

Heating the 25,000 cubic feet of air supplied per minute to a temperature of 1200° Fahr., its volume would be increased to 85,000 cubic feet; and, on the supposition that the furnace is blown by seven tuyeres, each seven inches in diameter, this torrid air would rush through each tuyere (under a pressure of 9 pounds per square inch) at the rate of 12,143 cubic feet, and having the enormous lineal velocity of 45,417 feet per minute. The velocity is over five times that of the most violent tornadoes, and the pressure is more than 25 times greater. Should a blast of equal pressure and velocity come from unfathomed space and envelop this earth, it is absolutely certain that no living beings or loose materials would be left upon its rock-ribbed skeleton, which, stripped of its flesh and blood, fields and forests, lakes and oceans, would be hurled into a new orbit and made to assume revolutions and rotations whose amplitude and duration it is impossible to imagine or describe.—*Popular Science Monthly.*

New Experiments in Magnetism.

It has long been known that a common sewing needle will float if carefully placed on a surface of water; also, that if the needle be magnetized, it will assume a position in the magnetic meridian. Iron and steel filings will also float, and they can be sprinkled upon the liquid surface nearly as well as upon a solid. If the pole of a magnet be brought near the floating particles, they will respond to the solicitations of the magnetic field in a very free and easy manner.

Let a strong U magnet have its poles brought near to the iron filings and they will at once arrange themselves in the well-known forms, the lines being plainly seen. The induction, of course, causes adjacent particles to assume opposite polarities and consequently touch each other when free to move. If, now, the field magnet be removed, the filings will retain their arrangement, and if it be in a vessel large enough to permit the rotation of the whole body, it will swing into the magnetic meridian. If it did not happen to be in it at first, thus showing the arrangement constitutes the magnet, and that, as a whole, it possesses a magnetic field upon which the earth's field can act.

Now bring gently near the floating magnet one pole of a bar magnet. If this be presented to one of the poles of the particles, it will be attracted toward it, and the whole body will rotate more or less, but this must be done slowly, else the arrangement of the filings will be broken up. The opposite pole will, of course, under similar conditions, exhibit repulsive action and the whole will swing about.

If, now, the magnetic pole be brought near to the middle of the arranged filings, some of the groups will be more or less disintegrated from the rest and will rotate upon a vertical axis and quite turn round. The opposite pole presented will cause them to rotate back again. Great numbers of these can be seen to turn thus whenever a pole is thus presented.

This phenomenon is evidently precisely the same in character as that illustrated at length by Ewing in his late investigations into the constitution of the magnets, wherein he used small magnetic needles mounted upon pivots. The above experiments can be tried in a saucer of water, but the whole is capable of being projected with the vertical attached to a lantern and the movements of all sorts seen upon a screen with ease and very little painstaking.—*Electrical Engineer.*

THE GULF STREAM AND CYCLONES.—Among the many theories which were given to us as fixed facts, and stored away as such in our memories during our schoolboy days, but which are being swept away one by one by later investigations, we shall probably have to class that which professed to describe so accurately the course and influence of the Gulf stream. The time-honored teaching of the old geographers that the full force of the current, after entering and making a complete circuit of the Gulf of Mexico, made its way northward through the cooler waters of the Western At-

lantic, and even affected the temperature of Europe, has been materially modified by the more careful observations of modern science. The view that is now favored, if not fully established by recent observers, is that the Gulf Stream as a current really begins at Florida strait and ends somewhere near the Grand Banks. The fact that the drift from the stream is found largely in the western part of the North Atlantic is explained by the influence of the prevailing winds, but Lieut. Pillsbury is thought to have shown that high winds do not interfere with either the velocity, position or direction of the stream itself. Patches of the stream drift have been found during the last few years closely packed along the eastern shores of the Middle and North Atlantic States. This has led some to fear that the Gulf Stream was shifting its position to one nearer the coast and that a gradual change of climate was the result. But Mr. Jacques W. Redway points out in a recent article that there has been a systematic and periodic change in certain of the elements of the stream ever since it had an existence; and he argues that the assumption that in a very long period of time the precession of the equinoxes may affect the position and direction of the line of maximum flow is a question of theory and not of fact. Mr. Redway admits that there is a remarkable correspondence between the track of this current and the cyclones of the North Atlantic, but asserts that positive proof of any connection between the two phenomena is lacking. The records of the Weather Bureau of the United States show that during the summer months, when the current of the Gulf Stream is putting forth its greatest strength, the cyclones come most frequently, and it is thought possible that the excess of moisture which hovers along the track of the stream may be the fuel to which the cyclones owe their energy.—*Toronto Work.*

ABSORPTION OF ORGANIC MATTER BY PLANTS.

In a communication by Prof. Calderon of the Institute of Las Palmas, Canary Isles, he contests the ordinary view that the nitrogen of the tissues of plants is derived entirely from the nitrates and ammoniacal salts absorbed through the roots. He does not, however, adopt the old theory that the source is the free nitrogen of the atmosphere, but rather the nitrogenous organic matter which is always floating in the air. The nutrition of plants he divides into three classes: *Necrophagous*, the absorption of dead organic matter in various stages of decomposition; *plasmophagous*, the assimilation of living organic matter without elimination, or destruction of any kind between useful and useless substances, such as the nutrition of parasites; and *biophagous*, the absorption of living organisms, such as that known in the case of insectivorous plants. A further illustration of the latter kind of nutrition is, according to Prof. Calderon, furnished by all plants furnished with viscid hairs or a glutinous excretion, the object of which is the detention and destruction of small insects. To prove the importance of the nitrogenous substances floating in the air to the life of plants, he deprived all of organic matter in the mode described by Prof. Tyndall, and subjected lichens to the access only of this filtered air and distilled water, when he found all their physiological functions to be suddenly suspended.—*Nature.*

A NEW COAL SAVING COMPOSITION.—A coal-saving composition which has been invented by Mr. W. C. Owston, of the Pontefract Coal-Saving Company, Limited, was tried last week, in Leeds. The composition is a chemical compound resembling fine sand, and one of the principal properties claimed for it is that when sprinkled on an ordinary fire, after it has been made up, it ensures thorough combustion, all the gas and tar, which in the ordinary way is allowed to pass off in smoke up the chimney, being consumed. It is also claimed that a fire so treated lasts longer, and throws out more heat. The mode of operand is very simple, all that is required to be done being to sprinkle about ½ ounce of the composition over the fire.—*Colliery Guardian.*

FREE TELEPHONES will soon be a possibility. In England the Bell Telephone patent has expired, and the Edison patents will soon expire, and there will then be free competition in that line of business, resulting in a greatly reduced rate for instruments. The long-suffering business public of the United States will be thankful when the 17 years life of the patent in this country expires, and that soulless monopoly is brought into competition with any manufacturers who may see fit to enter the field.

A COLD WAVE.—Prof. T. Russell defines a "cold wave" as a fall of 20 degrees in temperature in 24 hours over an area of 50,000 square miles, the temperature in some part of this area descending to 36°. During the past ten years there have been no less than 691 cold waves in the United States.

A BURNING TAPER uncovered for a single instant, during which it does not lose power amounting to the one-thousandth of a grain, would fill with light a sphere four miles in diameter so as to be visible from every part of the compass.

ALPINE GLACIERS.—A recent survey has established the number of glaciers in the Alps at 1255, of which 249 have a length of more than 4½ miles. The French Alps contain 144 glaciers, those of Italy 78, Switzerland 471 and Austria 462.

GOOD HEALTH.

La Grippe Epidemic.

La grippe, according to the report of the State Board of Health for February, is again upon us, and rapidly developing into a widespread epidemic, quite equal to that which prevailed during the winter of 1889-90. The present epidemic is characterized by its sudden onset and the intensity of its initiatory symptoms, the premonitory chill, the fever, headache, backache, pains in the bones and muscles, that more nearly resemble dengue, or haekhoe fever, than any other disease. Another feature peculiar to the present epidemic is the frequency with which cases occur in which the cough is almost entirely absent, and others in which pneumonia of a low type is almost certain to be developed. The debility accompanying the disease is invariably present and must be treated by stimulants liberally given. The origin of the disease being unknown, the power of the sanitarian over it is exceedingly limited, and consists chiefly in advising the avoidance of all depressing influences that might deteriorate the healthy constitution, or impair its strength.

In many cases it is accompanied by slight pneumonia or pleuro-pneumonia, which in feeble constitutions may assume a severe type. This may account for the unusual mortality from pneumonia during the month of February—160 deaths being counted in a population of 721,975.

La Grippe is a febrile disorder, and it usually ends with a slow convalescence. Its mortality when not attended or immediately followed by pneumonia, is generally small—not over two or three per cent of the cases. It is generally accompanied by loss of strength and depression of spirits. It appears to travel like cholera from east to west.

The Origin of La Grippe.

It is supposed to be occasioned by the presence in the atmosphere of a specific organism which enters the body in the air that is breathed, and rapidly multiplies until the food on which it lives is exhausted, when it perishes and disappears. Hence it is admitted to be both contagious and infectious. If this theory of its origin be sound, it follows that little good can be done by medicines, though they may mitigate some of the more annoying symptoms. The high priests of bacteriology are studying to discover some means of destroying this supposed yet undiscovered bacillus.

There does not appear to be much connection between la grippe and a common cold, except that the occurrence of a cold may so weaken the system as to make it more susceptible to the attack of la grippe bacillus. Hence care should be taken to avoid exposure. There is no need for especial alarm, but people, especially the aged and feeble, should be upon their guard against possibilities.

The Treatment of the Disease.

The symptoms of the approach of the disease are given above. We clip from a contemporary the following rules for treatment which will generally be found to apply to all cases. The first is to stop the chill with which the attack usually begins, and this should be done with hot bottles, and in obstinate cases with the use of a hot brick steeped in alcohol. At all costs, the temperature of the patients must be restored. This accomplished, the loss of strength caused by the disease should be met by a generous use of digestible and nutritious food. Physicians generally supplement this treatment by prescribing a number of drugs which may be of service or may not. The chances are that they will do no harm. The patient should remain indoors, in a room that is free from draughts and suitably warmed. He should, so far as he can, keep up his spirits by cheerful reading and conversation.

It was found last year that people who had had the grippe were left in a crippled condition when it disappeared. They remained for weeks feeble and liable to catch other diseases; they suffered terribly from depression of mind, and the nervous system remained out of order for quite awhile. These consequences of the malady are characteristic, and it is not easy to see how they can be prevented. Physicians have not succeeded as yet in discovering an antidote for nervous depression, and la grippe takes on that shape in the stage of convalescence. It leaves "the blues" behind it, and it is beyond the reach of modern art to dispel them.

The spread of this disease might no doubt be materially lessened if the public could be taught to look upon it as it does upon diphtheria and small-pox, and take the same precautions in isolating its victims as it does in cases of those diseases. A contemporary makes a good point, applicable to all contagious diseases, as follows: Another point upon which it might be well to inform the public is, that where an infectious or contagious disease occurs in a home and the washing of the patient's bedding or clothing is sent away to be washed without first having them thoroughly disinfected and the washerwoman or any of her family thereby become infected, they can recover damages in a court of law if not previously notified or warned that the clothing is infected. A few successful suits of this kind would engender caution and a realization of the fact that public protection must be afforded against infectious disease.

THE BUILDER.

The Sins of Architects.

A writer in *Popular Science Monthly* for December criticises some of our architects as follows: "In the search for the beautiful in architecture the demand for impressive facades, the taste for complicated ornament, and a most singular appreciation of the odd, the grotesque and the ugly, there is little attention paid to matters which seem self-evident and are of really vital importance. Windows are arranged to suit a symmetrical facade, whether they are just what are needed for the rooms or not, and even where it is possible little attention is given to the direction of sunlight in order that the living-rooms may receive the full benefit of the natural warmth, nor are those rooms where it is not needed or minor offices relegated to the exposed side. The most important external feature, the door, is seldom adjusted to the climate. Even in large offices buildings, hotels and churches, where there should be ample space for every structural convenience, the door is frequently of cramped dimensions, and instead of being preceded by a porch, which would be an integral part of the architecture, and which is absolutely essential in our long, cold, damp winters, is boarded up with "storm doors" that are not only hideous in design but an actual obstruction. With the rapid increase in the value of land which has taken place in all our large cities in late years, a wild fear lest any inch be wasted has resulted in a compactness of plan that is frequently painful. The housekeeper longs for the roomy closets and ample store-rooms of the old buildings; the fine hall that once formed an imposing and appropriate entrance, has given place to the narrow entry through which it is frequently impossible to carry the larger articles of furniture. The same difficulty is experienced in the sharp, frequent turns which characterize so many stairways. Bedrooms are pushed into corners where they seldom have the benefit of pure, free air and the heat of the sun, for no other reason than that space is required for ample reception-rooms and state apartments, which, though used comparatively seldom, are treated as the most important part of the house."

ABOUT FLOORS.—Why one finds so few good floors when architects never fail to make the proper specifications to obtain such, says the *Northwestern Builder*, is somewhat of a mystery to every one who suffers from bad floors, and this every one includes the man or woman who sweeps the floors, those who suffer from the dirt and dust they harbor, and especially those who carry off slivers in the soles of their shoes. Negligence is the principal reason for this state of facts, and both architect and carpenter are open to the charge. As perhaps three-fourths of all floors laid are of yellow pine, a material that gives better satisfaction than even the higher-priced hard woods, and as every architect and every carpenter knows how to obtain an almost perfect floor with this material, where does the negligence manifest itself? In the selection or acceptance of the material. Every board should have a straight or "comb" grain, and if the log is properly sawed, every board will have such a grain, just as quarter-sawing produces a grain of peculiar kind and beauty, but very few millers care to take the trouble to saw in this manner, and they will not as long as they can sell any kind of stuff for high-grade flooring. Floors to be carpeted are usually made of white pine, and to save a little labor they are usually nailed through instead of being nailed through the tongue. Some of the nails are almost certain to work up and a hole in the carpet is the result. Such things may seem to be small matters, but a multitude of them creep into a building and its occupants can never know the comforts of a well-built house.

WINDOWS, and their necessary adjuncts, are at the present time a matter of consideration for architects when formulating plans for future buildings. The old device of weights and cords has become so firmly established by usage that by superior merit only can any other appliance be substituted therefor. The Gardner sash balance seems to possess all the especial advantages of the weight and pulley system, but the defect of cords is overcome by the use of a steel tape in place of such cords. These tapes are galvanized, so as to prevent them from rusting and are provided with convenient attachments to both sash and weights. They hold the sash in any position, and when raised the upper sash is held in its place so that the lock will catch. Where a twisted or braided cord is used, the sash will drop a quarter or a half-inch—or just sufficient to prevent the sash-lock from taking effect.—*Ex.*

ROOF AND CHIMNEY.—There is no doubt but the form of a roof has much to do with the draught of a chimney. The flat roof offers no resistance to the passage of air, but as the pitch is increased, the current is more and more disturbed, until with a high-pitched and many-gabled roof it is broken into innumerable eddies, some of which are sure to curl down and force the smoke and gases in the flue into the rooms below. Chimneys on such roofs should be built higher than ordinarily.

USEFUL INFORMATION.

SOAPSTONE.—The term "earth-eaters" is applied to savages on the banks of the Orinoco and in New Caledonia, who eat a kind of steatite of a soft nature. Soft steatite forms excellent stoppers for the chemical apparatus used in distilling or subliming corrosive vapors. The powder is used also to diminish friction. Venetian talc is used for removing stains from woollen cloth. The fine varietles of talc when colored with the safflower forms a rouge for the toilet. In later years the mineral has been applied to many domestic uses. The old-fashioned wooden washtubs have almost disappeared from New York flat houses and dwellings. In place thereof is put in stationary washtubs built of soapstone with the usual faucets and traps. Through their use is saved much labor for domestics and tired mothers of families. The borders of registers and the slabs of fireplaces and under ranges are made of soapstone too. Laundries are putting in stationary wash-tubs. The use of soapstone for washtubs is a sanitary measure. The mineral does not absorb as in the case of wood. An ordinary iron tub will absorb grease. In cases of contagious diseases like scarlet fever, soapstone cannot absorb the germs in the filthy water left in washing garments worn by sick people. The old-fashioned tubs did absorb the germs. They might be dormant for a time, but there was danger that the germ might spring into life again. Among the articles which can be made from soapstone are bath tubs, fireplace lining, stove lining, griddles, foot-warmers, muff-stones, acid tanks, table tops, molding for organ pipes, sinks and pots for water lilies. It is used for wallscotting and for non-conductors on electric motors. In New Orleans and other southern cities it is used in the manufacture of coffins.

SHORT WEIGHT GOLD COIN BECOMING COMMON.—Short-weight gold coins are becoming annoyingly common in the Eastern States. This "shortness" is due to a species of robbery familiarly known as "sweating coins." From a careful examination of light pieces which are now being found, it is evident that the thief is not doing his work by the old hand method of shaking the coins in a bag and then gathering the dust by means of quicksilver, but that he has brought into requisition the agency of electricity. The service of an ordinary galvanic battery and some cheap acid is all that is necessary to conduct the operation by the electric process. The scheme is similar to that employed in plating with gold by electricity. The coin is placed in the fluid and attached to it are wires from the poles of the battery leading to another piece of metal prepared to receive, in the form of plating, the metal to be removed from the coin. The battery being set in motion, sufficient gold to form a plating is quickly transferred, and as it is removed uniformly from all parts of the coin, the liability of disfigurement is reduced to a minimum. The only effect is to blur the character slightly. About 50 cents' worth of gold can be removed in this way from a ten-dollar gold piece, without exciting the suspicion of the casual observer. To the skilled eye of an expert, however, the effect is generally apparent at a glance.

CLEANING COLORED WOOLENS.—Four ounces of white castile soap, four ounces of ammonia, two ounces of alcohol, two ounces of glycerine. Shave the soap in one quart of water over the fire. When dissolved add four quarts of rain water, and when nearly cold the other ingredients. Bottle and keep in a cool place. One cup of this mixture in two quarts of water will be sufficient for ordinary use. Now lay the goods on an old sheet, and iron rapidly and lightly on the wrong side, and then roll tightly on a certain pole or any round piece of wood. If this is carefully done you do away with the creases made by folding. For black silk or cloth dissolve one tablespoonful of borax and one tablespoonful of indigo in one pint of warm water. Sponge the pieces well and lay smoothly one above the other, and, if possible, put in the sun to dry.—*Ladies' Home Journal.*

FOR PAINTING WALLS OR OTHER OBJECTS EXPOSED TO DAMP.—A composition of very fine iron filings and linseed oil varnish is said to be much used in Germany; and, when the object to be painted is to undergo frequent changes of temperature, linseed oil and amber varnish are added to the first two coats. This paint may be applied to wood, stone or iron; in the case of the latter, it is not necessary to free it first from rust or oily matters.

DISTILLED SPIRITS CONSUMED IN THE ARTS. According to the new census report, the total quantity of distilled spirits consumed in the arts, manufactures, and medicine in the United States during the twelve months ending Dec. 13, 1889, was 10,976,842 proof gallons.

TO HARDEN FILES.—Rub a little hard soap across the teeth to keep from scaling; heat to a cherry red, and dip endwise in salt water; then dip in hot fresh water to remove any salt on the teeth, dry over the fire, and wet slightly with linseed oil on a rag.

THE COPPER MINES OF THE WHOLE WORLD are being taxed to their utmost to supply the demand for copper wire and the other apparatus used in the application of electricity.

STEAM BOILER NOTES.

Something About Safety Valves.

A writer on steam topics, Mr. A. N. Somerscales, says that "so long as a safety valve remains shut, the steam pressure acting on the underneath side of the valve is opposed by the weights of the load resting on the top, which may be either dead weight, a helical spring, or an arrangement of one of these acting through the agency of a lever. Now, either by calculation or by trial, it is possible to proportion the load to the area of the valve so that the valve shall be lifted off its seat when the steam has reached any particular pressure fixed upon as the blowing-off pressure."

What Happens When the Valve Opens.

When the valve opens the slightest amount of lift off the seat allows the steam to escape in all directions through the annular orifice between the edge of the valve and seat. Its velocity is very great—probably 800 feet per second. The steam in the immediate neighborhood of the valve seat escapes first, and its place is necessarily taken by other steam from the boiler, which also escapes. A current is thus set up not only through the orifice furnished by the valve, but also through the pipe leading to the same.

Now, a fluid will not commence to flow unless there is less pressure in front than behind. Therefore when the steam is rushing up the pipe leading to the valve seat, we may be certain that there is less pressure at the top of the pipes than at the bottom. In the case of a dead-weight valve, if it has to remain open and permit steam to escape, there must be as much pressure under the valve as balances the load on top. And as we know the pressure under the valve is less than the pressure in the boiler, the sole condition under which the valve can be kept open and allow steam to escape is that there must be some accumulation of pressure in boiler over and above the load on the valve.

If the valve is loaded to 110 pounds per inch, and the difference between the top and bottom of the pipe is four pounds, the pressure will be 114 pounds when blowing off.

To trace the action of the valve more closely, we may say that when the steam first begins to blow off, the valve will rise a very small distance off the face—so little, indeed, that the velocity of the steam up the pipe will be small and the reduction of pressure at the under side of the valve inappreciable. The small orifice thus opened being insufficient to relieve the boiler, an accumulation of pressure will result. The extra pressure acting on the valve will increase the lift until the reduction of pressure through the velocity of the steam in pipe is only just sufficient to balance the load on the valve as before.

If the boiler is still making steam faster than it is escaping, a further accumulation will occur and a further adjustment take place. But at any instant the pressure on the under side of the valve will always be 100 pounds above the atmosphere, even when the accumulation of pressure in the boiler is considerable.

Now, to prevent any considerable accumulation of pressure occurring when blowing off, it has always been the practice to make safety valves very much larger than the size of orifice actually required for the escape of all the steam which the boiler can make. If an area of about one-thirtieth of a square inch is actually required for the steam to blow through, safety requires an area of half a square inch in the safety valve.

Such being the practice, it follows that safety valves only need to lift a small fraction of an inch off their seats when blowing off, thus avoiding much accumulation of pressure due to the cause we have been considering.

THREE POUNDS of water per hour evaporated from each square foot of heating surface in a boiler is a fair average for a good boiler.

SUBSTITUTE FOR GUTTA-PERCHA.—A Portuguese gentleman, Senor da Costa, says *Invention*, is reported to have discovered an excellent and abundant substitute for gutta-percha, near Goa. It is the solidified fluid which issues from the *Nivul-cantem*, which grows wild in the Oconan diatrit, which is generally planted for bedges. It is insoluble in water, softens under heat, and hardens in the cold. It receives, moreover, and retains a given mold, can be cast into very thin sheets, and is capable of taking the minutest impressions upon its surface. Though white when it flows from the tree, in its dried state it is of a chocolate color, closely resembling gutta-percha. If this be true, the discovery is of enormous value.

SLIDING GROUND.—The *Nevada Herald* says: Below Boston Bar, near what is known as Keystone Flat, there is a tract of land of several acres, steadily sliding into the Yuba River. The amount of earth slowly moving into the river, and which will eventually be deposited in the valleys, shows that it is not hydraulic mining alone which creates debris, and this landslide is only one of the many to be found in the mountains and with which mining has no connection.

CAST-IRON TIES are now manufactured at Burrakur, Bengal, and at the works of the East Indian Company at Jamalpur, Bengal.

Passing Events.

The receipt here this week of the first ingots of tin ever made in this country, marks an era in the mining industry of California and of the United States. The tin came from the San Jacinto estate tin mines, San Bernardino county, where smelting operations have just commenced. The mines have been known many years, but litigation has prevented their development until now.

The Santiam mines, Oregon, are again attracting attention, and machinery is now going in to work the ores. This is an old district, but the old mines relocated are proving of good value.

The Legislature adjourned on Wednesday night. This Legislature has either been the most objectionable or else the most unfortunate the State has lately seen. And yet it has done some very good things, and it is not unlikely that a careful estimate, after the memory of the unfortunate "sensations" of the session has passed away, may show its work better than it now is credited with. Such is usually the case, and such is at all events a charitable view to take of it.

A President has been selected for the new university at Palo Alto, whose duties will commence in September, so the institution will soon be in running order.

South African Gold Mines.

On another page is a letter from a correspondent in South Africa, who sends us a very interesting account of the operations around Johannesburg. The gold output of the district was about 100,000 ounces larger last year than ever before and more mines are being found. Several California gold miners are out in that region in charge of works, among them Chas. Pringington of Oakland, a very experienced and skillful millman well known on this coast. He has charge of the very extensive works of one of the English companies mining for gold.

Our correspondent sent us official records of the Witwatersrand Chamber of Mines, a series of monthly returns showing the result of operations of the Witwatersrand companies producing gold. There are several reefs and about 40 producing companies. From these statements we compute the following table, omitting the names of the companies and stating totals and averages for the district for the months of last year:

Months,	Tons milled.	Number of stamps.	Days milled.	Yield of Gold.	
1890.				Total.	Per ton.
				£	\$ & c.
January.....	45,988	865	23.74	122,818	2 12 5
February.....	48,651	839	23.49	129,615	53 9
March.....	49,951	839	22.19	132,785	2 12 10
April.....	49,810	850	22.47	135,439	2 13 7
May.....	54,517	1,045	22.67	138,896	2 9 13
June.....	52,920	1,010	22.28	131,038	2 9 4
July.....	53,653	1,212	25.99	135,469	2 9 11
August.....	59,544	1,175	21.70	150,231	2 6 8
September.....	56,356	1,240	23.62	159,430	2 4 6
October.....	69,643	1,035	25.42	158,923	2 9 9
November.....	72,435	1,155	26.39	164,149	2 3 9
December.....	40,135	804	22.37	135,136	3 3 9

As stated, this table shows totals and averages of all the companies in the Witwatersrand field. January of last year the yield was 35,006 ounces, valued at £3 10s per ounce. January of this year the yield was 53,205 ounces. The field produces between eight and nine million dollars gold per annum. Numerous discoveries have been made of late, and the gold-producing area will doubtless be extended still farther.

California Tin.

This week the first ingots of tin ever made in California arrived from the mines of the San Jacinto estate, Cajalco, San Bernardino Co. These are what were known as the Temescal tin mines, which were discovered many years ago. Litigation and other causes have prevented the claims from being developed, but now an English company has purchased and equipped them for active work. Oil fuel is used in the furnace, this being much cheaper in that region than coal. The experiments with the reverberatory furnace and oil fuel seem to be successful. The concentration tests, elsewhere referred to in detail, are also points of interest.

California and Dakota are the two tin-ore producing regions of the United States. Tin ore was discovered here first, but for many years was not utilized. The existence of tin in the Black Hills has also been known some years, and we have on our desk a small tin ingot made from Dakota ore some four or five years ago. For some reason, however, the deposits of that region have not been put in a producing shape to put the tin on the market in this country. Possibly the success of the California experiment will lead to further development of the tin industry elsewhere.

YUMA.—The recent heavy floods in Arizona have demonstrated the impracticability of maintaining the Southern Pacific track on its present bed in the vicinity of Yuma. As stated before, only temporary repairs have been made on a portion of the line damaged at this point, and in all probability Yuma has seen its last winter as a station on the line of the Southern Pacific.

THE Iron-Molders Union ordered a strike of the 16 molders at the Pacific Rolling Mills, Wednesday. The Rolling Mills employ 900 men, of whom only 16 were molders and these 16 have quit work.

WORKS on the plan of the Butters' reduction works at Kennet, Shasta county, will soon be put up in Mexico. Mr. Butters is now in Africa, putting up chlorination works there on his plan.

SEVERAL electric railroads are projected in Oakland, and one of them is about completed.

The Patent Centennial Celebration.

In the PRESS of March 14, an account was given of the coming celebration of the "Beginning of the Second Century of the American Patent System," which is to take place at Washington on the 8th, 9th and 10th of April. This is the first time in the history of the Republic that the inventors and manufacturers of patented articles have celebrated, and elaborate arrangements have been made by the committees having the affair in charge. The railroads leading into the National Capital have reduced their rates for the occasion, and a great crowd is expected. President Harrison will open the celebration, and the literary exercises will be presided over by some of the most eminent inventors in the country. Twenty addresses upon the different phases of invention will be delivered by men who are famous as masters of the subjects they will discuss. A national association of inventors and manufacturers of patented articles will be organized. There will be a reception at the Patent Office by the Secretary of the Interior and Commissioner Mitchell, at which it is expected Cyrus W. Field, Thomas A. Edison, George Westinghouse, George M. Pullman and others will assist. There will be a military parade, a grand excursion to Mount Vernon, a planked shad banquet at Marshall hall, near Mount Vernon, and the Navy Yard, the National museum, the Patent Office and other interesting national establishments will be open to the visitors.

The different public meetings will be presided over by the President of the United States, the Secretary of the Interior, the President of the National Board of Trade, the secretary of the Smithsonian Institute and Prof. Alexander Graham Bell.

April 10th is the anniversary of the signing of the first American Patent law: "An Act to Promote the Progress of the Useful Arts," by George Washington.

In addition to the expected addresses from prominent inventors and manufacturers at the meetings for the organization of the National Association, addresses upon the following subjects are promised at the public meetings:

Edward Atkinson, Ph.D., LL.D. of Massachusetts.—Invention in Its Effects upon Household Economy.

Dr. John S. Billings, Curator U. S. Army Medical Museum.—American Invention and Discoveries in Medicine, Surgery and Practical Sanitation.

Hon. Samuel Blatchford, Justice of the Supreme Court of the United States.—A Century of Patent Law.

Cyrus F. Brackett, M. D., LL.D., of New Jersey, Henry Professor of Physics, College of New Jersey, Princeton.—The Effect of Invention upon the Progress of Electrical Science.

Hon. Benjamin Butterworth of Ohio, U. S. House of Representatives.—The Effect of our Patent System on the Material Development of the United States.

Octave Chanute of Illinois, President of the American Society of Civil Engineers.—The Effect of Invention upon the Railroad and other means of Inter-Communication.

Professor F. W. Clarke, S. B., of Ohio, Chief Chemist U. S. Geological Survey.—The Relations of Abstract Scientific Research to Practical Invention, with Special Reference to Chemistry and Physics.

Hon. John W. Daniel of Virginia, U. S. Senator.—The New South as an Outgrowth of Invention and the American Patent Law.

Major Clarence E. Dutton, Ordnance Department, U. S. A.—The Influence of Invention upon the Implements and Munitions of Modern Warfare.

Thomas Gray, C. E., B. Sc., F. R. S. E., of Indiana, Professor of Dynamic Engineering, Rose Polytechnic Institute, Terre Haute.—The Inventors of the Telegraph and Telephone.

Professor Otis T. Mason, Ph.D., of Virginia, Curator U. S. National Museum.—The Birth of Invention.

Hon. Charles Eliot Mitchell of Connecticut, Commissioner of Patents.—The Birth and Growth of the American Patent System.

Hon. O. H. Platt, LL.D., of Connecticut, U. S. Senator.—Invention and Advancement.

Col. F. A. Seely of Pennsylvania, Principal Examiner U. S. Patent Office.—International Protection of Industrial Property.

Hon. A. R. Spofford, LL.D., Librarian U. S. Congress.—The Copyright System of the United States: its Origin and its Growth.

Hon. Robert S. Taylor of Indiana.—The Epoch Making Inventions of America.

Robert S. Thurston, A. M., LL.D., Doc. Eng., of New York, Director and Professor of Mechanical Engineering, Sibley College, Cornell University.—The Invention of the Steam Engine.

William P. Trowbridge, Ph.D., LL.D., of New York, Professor of Engineering School of Mines, Columbia College.—The Effect of Technological Schools upon the Progress of Invention.

Hon. Edwin Willits of Michigan, Assistant Secretary of Agriculture.—The Relation of Invention to Agriculture.

Hon. Carroll D. Wright, M. A., of Washington, Commissioner of Labor.—The Relation of Invention to Labor.

THE Albany M. & M. Co. has let a contract for \$30,000 worth of milling machinery for the Santiam mines, Oregon.

City Libraries.

The ceremonies of laying the corner-stone of the new Mercantile Library building occur on Saturday afternoon of this week, at the corner of Van Ness and Golden Gate avenues. Work on the building is being rapidly pushed, and already the first-story walls are nearly finished. The frontage on Van Ness avenue is 120 feet, and that on Golden Gate avenue 109 feet. The building will be three stories high, but so constructed as to admit of extra stories when desired.

The location is one where plenty of light can be obtained, a very desirable feature in library quarters. The library proper will be on the ground floor, and the second and third stories will be used for reading and chess-rooms. The cost of the building is estimated at \$100,000. When it is ready for use large additions of books are to be made, and an increase of membership is expected.

The managers of the Mercantile Library Association deserve great credit for the energy displayed in again placing the association on a proper basis. At one time it looked as if the institution would pass out of existence altogether. But with a fine building in a good location it will soon be restored to its former usefulness.

Another effect this move will have is to "stir up" the Mechanics' Institute people in the direction of permanent, enlarged quarters. There has been talk of this for a dozen years or so until many people have lost patience. The present building is old and unsuitable. Money has been added from the proceeds of fair after fair, and a good exhibition building put up, but the old library building continues in use, with its lack of space and all its inconveniences. With all its available assets, it would seem that a fine building with all modern conveniences, could be procured without further delay. The library of the Mechanics' Institute is superior in class and number to that of the Mercantile, but it is not apt to remain so very long if the latter has the "hook" its new building should give it. It is time for the Mechanics' Institute directors to take positively active steps in the direction of a new building, and not delay the matter much longer.

The Stanford University President.

Senator Leland Stanford has chosen for president of his new university Dr. David S. Jordan, who has been president of the Indiana University for the past seven years. The term of office at Palo Alto will begin next September, the salary being \$10,000 per annum and residence.

Professor Jordan is a scientist of acknowledged ability and standing, and has had also abundant experience as an educator. He is a broad-minded man of great energy and activity, who should be just the one to organize and equip the new institution of learning. The writer had the pleasure of forming the acquaintance of Prof. Jordan some years ago when he was in California collecting and identifying the fishes of this coast, and at that time became impressed with his earnestness and energy.

Professor Jordan is well known to all scientific men by his work in his chosen specialty, ichthyology. He was graduated from Cornell University in 1872, became instructor in marine botany at Pinkney two years later, and also took a medical degree at Indianapolis. As an expert on fishes, his services were secured by the Government in 1879-81 in taking a census of marine industries on this coast. He discovered many new varieties of fish on the California coast. He is recognized abroad as one of the leading authorities on North American fishes, and he has published a large number of papers on American fishes and a "Manual of the Vertebrates of the Northern United States." His collection of fishes is the largest private collection in the world. For several years he has been president of the Indiana State University, having been selected for the position because of his large executive capacity. He is about 40 years of age.

TRANSFER OF LEAD.—It is reported in New York that very large transfers of lead have been made this month. At times there has been a delay of 10 days before the stock could be taken from the transfer office on account of the large transfers.

Concentrating California Tin Ore.

(Concluded from page 193)

working, and instead of a No. 8 screen, a No. 12 (equal to a 48-mesh screen) was placed at the battery.

The concentrates yielded 70 per cent of tin metal. The tailings were found to contain, per ton of tailings, 2.6 lbs. cassiterite, equal to 1.82 lbs. of tin metal.

As you see, our general average of losses is below .1 of 1 per cent, or below .001, which is the least result ever obtained in dressing tin stuff. The best concentration work of Cornwall, England, loses .3 of 1 per cent or 6 pounds per ton.

Our tailings do not contain 2 pounds per ton, and this result is obtained with only one handling. During the first run with the Frue, 51,400 lbs. of ore from the old dump have been run through, producing 5713 lbs. concentrates, which is equal to a yield of 11.11 per cent of cassiterite, which contained 69.2 of tin metal, showing an average yield of 7.69 per cent of tin metal.

On February 18th we started the Woodbury concentrator, and the pulp of the battery was divided equally between the two concentrators.

See statement attached hereto. I made several other tests during this run with the same comparative results, showing that the Frue tailings are between three and four times poorer than those of the Woodbury.

I do not consider the Woodbury machine as well constructed as the Frue, and it is more liable to get out of order. The distributor does not work in a satisfactory manner at present, and this defect can be easily remedied, and one made to equally distribute our tin as desired. Respectfully submitted, HENRY MATHEY, Sup't.

Cajalco March 3, '91.

bury concentrator handled only one-half the pulp from the battery (5 stamp), or 6 tons per day, and could handle no more with good results, showing the error in the advertisement of the Woodbury concentrator, in which its capacity is claimed from 12 to 15 tons per day.

The Frue concentrator used was the regular four foot, plain belt machine. It handled 6 tons per day, which is the usual amount claimed for it.

Messrs. Adams & Carter, agents of the Frue concentrator, have in addition the following to say: "Since the above report was made out, an expert from Cornwall has examined the concentrations from each machine and has stated that the concentrations from the Woodbury machine were not clean enough to smelt and that they must be re-concentrated, which was done on the Frue. He also stated that the Frue concentrations were all right. Although the Woodbury concentrator has been running less than two months (it was started up Feb. 18th), Mr. Woodbury had to send down a complete set of new belts on March 22d, as the other set was fast going to pieces."

Adjustable Perch for Bird-Cages.

John F. Sweeney of 632 Market St., this city, has patented, through the MINING AND SCIENTIFIC PRESS Patent Agency, a medicated adjustable perch for bird-cages, which forms a convenient and valuable improvement for the home

shown roughened and is medicated so that the birds are always kept healthy and protected from vermin.

Each perch may be raised or lowered or held at any desirable point by the frictional pressure of the wires upon the holder B. By this construction the perches are easily supported within the cage and in proper positions with relation to each other, so that the bird can easily fly from one perch to the other without danger of breaking or damaging its feathers; and no perch need be placed over another one so as to become soiled or dirty. The perches are thus kept clean and do not need frequent washing.

Axtell's Railway Crossing.

Walter M. Axtell of Fruitvale, Alameda county, has obtained through the MINING AND SCIENTIFIC PRESS Patent Agency a patent on an improved railway crossing which is herewith illustrated. The advantages of this crossing over others of its class are that it presents at all times an absolutely continuous track for both the crossing and the crossed rails. All the rails composing it are solid and unbroken throughout, connection between the end of the inner section of the crossing rail and the head

The normal position of the guard is close up to the inner side of the rail to be crossed. The outer section of the crossing rail comes up close to the outer surfaces of the rail to be crossed, and the two inclined planes are close to the surface of the main-line rail. Now a wheel traveling upon the crossing track and approaching the main-line track to be crossed, the flange runs up on the inclined plane, and across the main track, on to the inclined plane of the guard and down said plane until the tread of the wheel again rests on the head of the intervening section of the crossing rail. As it reaches the other side, the flange travels up the opposite inclined plane of the opposite guard across the rail and down the inclined plane of the outside section until the tread of the wheel again crosses down on to the head of the outside section of the crossing rail. The wheel, in moving on the inclined plane, travels on its flange only about one-fifth of its circumference on each side. It will thus be seen that a continuous crossing track is provided. Nor does this interfere with the use of the track to be crossed, for the reason that as a wheel approaches on said track, its flange, entering behind the inwardly curved arm of the guard, presses the whole of said guard backward from the rail,

AXTELL'S PATENT IMPROVED RAILWAY CROSSING.

Mr. Henry Mathey, Sup't. San Jacinto Estate, Ld., Cajalco, Cal.—DEAR SIR:—The foregoing report I consider thoroughly consistent with the results obtained in our tin-test mill, during the time and manner stated by you.

I have been a daily as well as interested observer of the workings of the two machines named, and feel justified in indorsing your conclusions. Very truly yours, E. N. ROBINSON,

General Manager San Jacinto Estate (Limited). Woodbury Concentrator vs. Frue Concentrator—Comparative Tests.

WOODBURY CONCENTRATOR.

Tailings contain per ton of 2000 pounds avoirdupois. Feb. 24, Test No. 1, 19 lbs. tin oxide, equal to 13.3 lbs. tin metal; Feb. 28, A. M., Test No. 2, 4.4 lbs. tin oxide, equal to 3.08 lbs. tin metal; Feb. 23, P. M., Test No. 3, 10.8 lbs. tin oxide, equal to 7.66 lbs. tin metal; March 2, Test No. 4, 9 lbs. tin oxide, equal to 3.43 lbs. tin metal; average, 9.775 lbs. tin oxide, equal to 6.842 lbs. tin metal.

Concentrates yielded 66% tin metal. They contain 1.7% of iron. Concentrates of Run No. 4, 67% tin metal.

FRUE CONCENTRATOR.

Tailings contain per ton of 2000 pounds avoirdupois. Feb. 24, Test No. 1, 4.4 lbs. tin oxide, equal to 3.08 lbs. tin metal; Feb. 28, A. M., Test No. 2, 3 lbs. tin oxide, equal to 2.1 lbs. tin metal; Feb. 23, P. M., Test No. 3, 2.4 lbs. tin oxide, equal to 1.65 lbs. tin metal; March 2, Test No. 4, 1.8 lbs. tin oxide, equal to 2.3 lbs. tin metal; average, 2.9 lbs. tin oxide, equal to 2.03 lbs. tin metal.

NOTE.—In these tests the cassiterite, being very clean, is figured as containing 70% of tin metal. Concentrates yielded 72% tin metal. They contain 1.26% of iron. Concentrates of Run No. 4, 66% tin metal. Sample for Test No. 4 was taken by myself. Sample for test No. 2 [was taken by Mr. Brownell, agent for the Frue. Sample for Test No. 3 was taken by Mr. Woodbury. Sample for Test No. 4 was taken by myself.

During the Test No. 4 the two machines were run by one of our engineers, Mr. Perrin. Since we have started running the two concentrators, 36 tons of ore have been crushed from the old dump. Signed, HENRY MATHEY.

NOTE.—As can be seen by the foregoing, the Wood-

comfort of birds in cages. The perch (which is shown in various positions within the cage in Fig. 1) is clearly shown

ADJUSTABLE MEDICATED BIRD-CAGE PERCH.

on a larger scale in the detached view, Fig. 2. B is the grooved holding-block fixed to one end of the perch so that the latter projects at right angles from it. By springing the wires of the cage slightly apart, the block B can be inserted between them, and it and the perch will be held at any desired height by the pressure of the wires in the grooves in the edges of the block. That portion of the perch nearest the end is

of the crossed rail being made by sliding planes located in the movable guard, which presents always a solid track for the crossing road and is pressed backward out of the way by a wheel traveling on the crossed rail, immediately springing back into place again after such passage.

The out shows both T and flat rails crossing a T rail, one of each inner section being closed (as in normal position) for a wheel traveling on the crossing rails, and one of each sprung open as it would be with a wheel passing on the crossed rail.

The rails of the crossing track are provided with an underlying shoe or stringer extending several feet on each side of the track to give a firm and continuous foundation for the crossing tracks and preventing springing or jolting. The movable guard consists of two inwardly-curving arms having a notch or groove at their middle to fit up to and slide beside the head of the intervening or middle section of the crossing rail, backwardly extending braces and connecting pieces joining the inner ends of the middles of the arms with the rear ends of the braces and fitting into and sliding in the web of the crossing rail on each side. This guard has a sliding movement and springs hold it up close to the inner surface of the rail of the track to be crossed. The middle portion of the guard is provided with an inclined plane, the upper end of which lies flush with the head of the rails of the other track. The inner side of the crossing rail is provided with a corresponding inclined plane, as shown.

so that the flange can travel by it without interference, and as soon as it has passed, the springs throw the guard back again to its normal position to close up the joint of the crossing track.

The inventor claims that it is impossible for this crossing to get out of order so far as to cause any damage or cessation of traffic, there being no complicated mechanism about it, and no accident (traceable to principle and construction) could possibly happen which would cause it to present at any time an obstruction to either crossing or crossed rails.

Another point in its favor is that each separate movable guard (i. e. sliding guard and inclined planes on each end of each inner section of crossing rail) works entirely independent of the others, not one of them depending upon the working of any other part of the crossing. This principle is not confined to the T rail alone, but is applicable to any form. It is not necessary to cut or at all interfere with the rails of the track crossed. While the first cost of this crossing may be a little greater than that in ordinary use, it will save in wear and tear on rails and rolling stock several times its cost in the course of a year.

JOHN ROACH, the well-known optician of this city, died last week in his 70th year. As an instrument-maker, he established an enviable reputation among engineers. Mr. Roach was well liked by all with whom he came in contact, by reason of his genial manner, good nature and strict integrity.

Rose's Mechanical Drawing Self-taught.

FOURTH EDITION.
Thoroughly Revised and Corrected.
RECENTLY PUBLISHED.

Mechanical Drawing Self-Taught; Comprising Instructions in the Selection and Preparation of Drawing Instruments, Elementary Instruction in Practical Mechanical Drawing; together with examples in Simple Geometry and Elementary Mechanism, including Screw Threads, Gear Wheels, Mechanical Motions, Engines and Boilers. By Joshua Rose, M. E. Illustrated by 330 engravings. Fourth edition thoroughly revised and corrected. 8vo. Price.....\$4.00

BY THE SAME AUTHOR:

Modern Steam Engines. An Elementary treatise upon the Steam Engine, written in plain language for use in the workshop as well as in the drawing office; giving full explanations of the construction of Modern Steam Engines, including diagrams showing their actual operation; together with complete but simple explanations of the operations of various kinds of valves, valve motions, link motions, etc., thereby enabling the ordinary engineer to clearly understand the principles involved in their construction and use, and to plot out their movements upon the drawing board. By Joshua Rose, M. E. Illustrated by 422 engravings. In one volume, quarto, 321 pages. Price.....\$6.00

The Complete Practical Machinist. Embracing Lathe Work, Vise Work, Drills and Drilling, Taps and Dies, Hardening and Tempering, the Making and Use of Tools, Tool Grinding, Marking out Work, etc. By Joshua Rose, M. E. Illustrated by 858 engravings. Fifteenth edition thoroughly revised and in great part rewritten. 12mo. 439 pages. Price.....\$2.50

The Slide Valve Practically Explained. Embracing Simple and Complete Practical Demonstrations of the Operation of each element in a Slide Valve Movement. By Joshua Rose, M. E. Illustrated by 35 engravings. 12mo. Price.....\$1.00

Steam Boilers. A Practical Treatise on Boiler Construction and Examination. For the use of Practical Boiler Makers, Boiler Users and Inspectors; and embracing in plain figures all the calculations necessary in Designing and Classifying Steam Boilers. By Joshua Rose, M. E. Illustrated by 73 engravings. 8vo. 250 pages. Price.....\$2.50

Illustrated Circulars, giving the full tables of contents of all the above works, sent free to any one who will apply.

The above or any of our Books sent by mail, free of postage, at the publication prices, to any address in the world.

Our new revised Descriptive Catalogue of Practical and Scientific Books, 87 pages, 8vo., and our Catalogue of Books on Steam and the Steam Engine, Mechanics, Machinery, and Dynamical Engineering, and other Catalogues, the whole covering every branch of Science applied to the Arts, sent free and free of postage to any one in any part of the world who will furnish his address.

CONTENTS.—Motive Power—Transmission of Power. Quarrying—Prospecting, Shaft-sinking, Coal-cutting, Pumping, and Ventilating Machinery—Lighting—Hauling and Hoisting Transport—Reducing—Dressing—Miscellaneous.
Price \$21.00. Circulars and Catalogues on application.

E. & F. N. SPON, Publishers,

12 Cortlandt St., New York.

The instrument represented in the above cut is a new and grand little invention, being designed to save life and limb, and innumerable lawsuits, by doing away with the dangerous operation of digging out wet and unexploded loads where Giant Powder is used in mining. The little instrument crimps the cap onto the end of the fuse firmly and absolutely Water-tight. It is also used for cutting the fuse. They are neatly gotten-up of the finest cast steel, nickel plated. Price, \$1.50 each.

N. W. MOODEY, Fresno, Cal.

BACK FILES OF THE MINING AND SCIENTIFIC PRESS (unbound) can be had for \$3 per volume of six months. Per year (two volumes) \$5. Inserted in Dewey's patent binder, 50 cents additional per volume.

PACIFIC ROLLING MILL CO.,

Superior Wood and Metal Engraving, Electrotyping and Stereotyping done at the office of this paper.

MARKET REPORTS.

Local Markets.

SAN FRANCISCO, March 25, 1891.

General trade is reported fairly active, with a number of distant buyers in the market. Among iron workers, business is reported better than at this time in 1890. The local money market is easy, with collections in all parts of the coast reported good. The recent advance in prices of cereals and better freight facilities allowed Washington and Oregon farmers to sell their grain to good advantage. This, together with marketing of other products, eased the money market up north. In this State farmers are reported to be, as a rule, easily circumstanced. The weather for growing crops continues unusually favorable.

QUICKSILVER—Receipts the past week aggregate 115 flasks. The demand is fair. The market appears to have a more settled tone.

MEXICAN DOLLARS—The market is barely steady around 78¢ cts. The steamer city of Peking for Hong Kong left on the 21st, taking out \$157,840.

SILVER—Department purchases in this month are reported as follows:

Date.	Offered ounces.	Purchased ounces.	Price paid per ounce.
March 2.....	1,480,000	105,000	\$.93250 to \$.93750
March 4.....	745,000	745,000	.93500 to .93750
March 6.....	1,000,000	278,000	.93250 to .93350
March 9.....	1,109,000	570,000	.93250 to .93700
March 11.....	355,000	355,000	.93700 to .93900
March 13.....	670,000	303,000	.93900 to .93950
March 16.....	—	377,000	.93900 to .93950
March 18.....	662,000	412,000	.93900 to .93900
March 20.....	1,204,000	259,000	.93925 to .93940
March 23.....	1,204,000	526,000	.93940 to .93900
March 25.....	533,000	229,000	.93900 to .93920

Total..... 4,167,000
* Purchases over the counter during the week ending March 7th—407 ounces.

The monthly quota of 4,500,000 ounces will probably be met on to-morrow (Friday) Department day. The market has been receding, why, no one appears to have any valid reason. Eastern advances report more foreign buying, while our English exchanges are confident of an increased demand this spring from India. The steamer that sailed home on last Saturday for China, took out 161,700 ounces for Bombay. This, with the preceding shipment aggregate about 187,000 ounces in this month. It is claimed that other shipments will follow.

The decline in silver can doubtless be traced to the bug-a-boo cry over the Treasury charging for withdrawal of gold bullion from government assay offices or mints. The tempest in a teapot raised over this action of the Treasury, has been formed by speculators in silver, and all securities whose values are grounded on the market price of silver. Had it not been for this speculative influence the last Congress would have given us free coinage. It is claimed that manipulators of mining shares are strong opponents of free coinage.

BORAX—The market is steady, with a good demand from the East.

LIME—Receipts the past week aggregate 7538 bbls, and exports by sea 1730 bbls, of which 1650 bbls went to Honolulu. The demand the past week showed an enlargement, due to more improvements in various parts of the State.

TIN—Imports the past week aggregate 3858 ingots from Australia. The market is reported essentially unchanged since our last week's review.

LEAD—The market is reported unsettled with cutting in prices still in order. Judging from the tone of our eastern advices we can reasonably look for an improvement before the spring months pass.

IRON—Imports the past week aggregate 100 tons from Irondele. The local market is heavy and unsettled. Dealers are carrying large stocks, while consumers are not disposed to buy beyond current requirements. Shotts & Thomas are about out of market. Although no changes in quotations are made, yet it is claimed that orders can be placed for spot parcels at less than quoted by us.

COAL—Imports the past week aggregate as follows: Tacoma, 6000 tons; Departure Bay, 5500; Nanaimo, 2445; Seattle, 2860; total, 16,805. The market for spot is unchanged. The consumption is said to be free for the season, but the stock, coast supply and Australian on the way, are large. Cargo buyers are not willing to enter the Australian markets for shipment at present selling offers. They claim that after the bulk of the wheat surplus of Australia is shipped, vessels will offer freely for coal loading to this port, which will bring about lower selling offers for coal.

Eastern Metal Markets.

By Telegraph.

NEW YORK, March 26.—The following are the closing prices the past week:

	Silver to Silver in London.	Copper.	Lead.	Tin.
Thursday.....	45 1-16	93 1/2	13 90	4 37 1/2
Friday.....	45 3-16	99	13 90	4 37 1/2
Saturday.....	45 3-16	93 1/2	13 90	4 37 1/2
Monday.....	45 1-16	98 1/2	13 90	4 40
Tuesday.....	44 1/2	97 1/2	13 85	4 37 1/2
Wednesday.....	44 1/2	97 1/2	13 85	4 37 1/2

Borax active and firm, with a fair supply of California powdered at 33¢ concentrated, 35¢ in car lots and 38¢ jobbing. In Quicksilver there has been a light trade at 63¢@64¢. Iron is barely steady. Copper continues unsettled. Tin has a firmer tone. Lead is steady.

Coal and Coke.

List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific Coast.

FOR WEEK ENDING MARCH 17, 1891.

- 448,330.—DEVICE FOR CONTROLLING HORSES—E. J. Fraser, S. F.
448,348.—WINDMILL—E. L. Kenoyer, Hanford, Cal.
448,526.—WASHING MACHINE—Lamborn & Rickards, Dixon, Cal.
448,357.—CHAFF SEPARATOR FOR THRASHERS—G. E. Minges, Atlanta, Cal.
448,363.—PRUNING IMPLEMENT—Perry & Dixon, Santa Rosa, Cal.
448,366.—HORSESHOE GAGE—W. C. Price, Woodburn, Or.
448,369.—VAPOR ENGINE—D. S. Regan, S. F.
448,462.—BEARING BOX—Geo. St. Pierre, Oakland, Cal.
448,467.—WINDOW SCREEN—Frank Walker, Los Angeles, Cal.
448,394.—SEPARATOR—F. H. Wheeler, Santa Barbara, Cal.
448,287.—CABLE GRIP—Wood & Fowler, Los Angeles, Cal.

The following brief list by telegraph, for Mar. 24, will appear more complete on receipt of mail devices:

- California—Nicklaus Anderson, Marysville, portable elevator; Newton M. Bell, S. F., manufacturing borax; William F. Bowers, S. F., swing hose reel; James Martin, Temescal, flower holder; Sidney W. Miller, Pasadena, flush tank; Ernest Natic, S. F., gas engine; Ernest L. Ransome, S. F., illuminating panel in concrete floors; John H. Wallace, S. F., switch stand; Oregon—Arthur Conklin, Grant's Pass, fruit dryer; Evan W. Jones, Portland, lathe for turning shafts.
Nora.—Copies of U. S. and Foreign patents furnished by Dewey & Co., in the shortest time possible (by mail for telegraphic order). American and Foreign patents obtained, and general patent business for Pacific Coast inventors transacted with perfect security, at reasonable rates, and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

DEVICE FOR CONTROLLING HORSES—Edwin J. Fraser, 112 Kearny, S. F. No. 448,330. Dated March 17, 1891. This device is intended for controlling spirited, vicious, or hard-mouthed horses, and it consists of pads adapted to press upon and close the nasal passages, and a means by which said pads are actuated in connection with the bit and reins so that the operation of the device will be automatic, acting to compress the nasal passages when the horse commences to pull too hard and instantly relieving itself when he becomes quiet.

MANUFACTURE OF BRICKS—Ernest L. Ransome, S. F. No. 447,972. Dated March 10, 1891.

Under the process of manufacturing unburned bricks which is described in the patent granted to the same inventor in July, 1885, a chemical action takes place between the lime or its equivalent and the silica of the ashes or their equivalent, which are used in the manufacture of the bricks. Such chemical action results in the hardening of the bricks, and this action is necessary to the success of the process both as the same is described in the former patent and as it is now improved. The present invention includes the discovery that the chemical action mentioned will be greatly facilitated if the bricks are immersed in water after they are molded and pressed; also, in the further discovery that such chemical action will be still further accelerated by having present in the material during such chemical action some of the soluble alkaline salts which naturally exist in the ashes of ordinary wood and coal; also, in the discovery that by the treatment described in the patent, a valuable solution of soluble salts can be incidentally and cheaply produced as a by-product during the manufacture of the unburned bricks. Under the process described in the previous patent, the soluble salts which were contained naturally in the ashes were removed before the material was molded. Under that patent, the molded bricks were not immersed in water. In the present improved process or method of treatment, the ashes are mixed with the lime as described in the previous patent, except that the ashes are not washed. The mixed material is then moistened just enough to make it adhere together in a mass. In this condition the material is molded and pressed into bricks, blocks or other forms, as desired. By exposing these molded and pressed bricks or blocks, while they are moist, to the atmosphere, they will soon become sufficiently hard to endure immersion in a water bath without danger of being disintegrated thereby. When the bricks are thus sufficiently hardened, they are immersed in batches in baths of water.

PRUNING IMPLEMENT—James W. Perry & Robt. H. Dixon, Santa Rosa, Sonoma Co. No. 448,363. Dated March 17, 1891. This invention relates to the general class of pruning shears and especially to that sub-class having a sliding or movable fulcrum between the opposing members, whereby what is known as a "draw cut" may be had. By the peculiar construction the blade has its longitudinal movement independent of the handles, which latter therefore remain in the same position and do not move lengthwise, as is customary with one or both handles in other form of shears wherein a sliding fulcrum is employed to provide for a draw cut. Therefore these shears are less tiresome to use, as the handles do not move lengthwise in the hand but remain stationary in that respect.

SEPARATOR—Fairfax H. Wheeler, Santa Barbara. No. 448,394. Dated March 17, 1891. This is a machine specially adapted for cleaning wheat and the cereals and leguminous seeds by separating them from the particles of dirt and other foreign material. The principle of separation involved in this device is that of frictional contact. Separation which depends on differences in size and upon differences in weight cannot be had where such differences do not exist. Thus with cereals and pulse it often happens that particles of dirt and rock have equal size and weight with the grains or seed of the material to be saved; and such particles have not the

same character of surface, and by this is meant not particularly form or shape, but smoothness and roughness. As a matter of fact, the surface of grains and seeds is much smoother than that of the particles of dirt and rock which are mixed with them. This invention is based on this fact; and its object is to separate thoroughly the foreign particles from the seeds and grains and even to separate out imperfect and mutilated grains and seeds, and branches, twigs, etc.

Successful Patent Solicitors.

As Dewey & Co. have been in the patent soliciting business on the Coast now for so many years, the firm's name is a well-known one. Another reason for its popularity is that a great proportion of the Pacific Coast patents issued by the Government have been procured through their agency. They are, therefore, well and thoroughly posted on the needs of the progressive industrial classes of this Coast. They are the best posted firm on what has been done in all branches of industry, and they have a great advantage, which is of practical dollar and cent value to their clients. That this is understood and appreciated, is evidenced by the number of patents issued through their SCIENTIFIC PRESS Patent Agency (S. F.) from week to week and year to year.

THERE is some excitement at Glenbrook, Lake Tahoe, over the discovery of rich gold-bearing ore in the vicinity. Numbers of men are out on snow-shoes looking for quartz.

Mining Share Market.

Mining shares the past week set back from Thursday morning to the close of the informal session on Saturday. Potosi and Bullion led in the break under an inside raid. The break-neck fall in the prices of other stocks to throw their holdings on the market, of which manipulators took advantage to buy at lower prices. The decline ranged from 25 to 50 per cent. On Monday under news from Virginia that Con. Virginia's assays were higher, there was a lively jump in the latter stock, causing the entire list to move in sympathy. Since then the market has fluctuated to slightly higher prices. Yesterday (Wednesday) afternoon, Overman surprised the street by one of its mysterious moves.

The feature of the market for outside mining shares, has been a steady up move in the Tuscaroras. As these stocks are reported well in hand, and several of the mining companies have considerable rich ore stored for milling, a good bull move can be made by insiders.

Virginia papers, notably the *Enterprise*, appear to be hedging on the one ledge theory, and getting ready to champion the MINING AND SCIENTIFIC PRESS, well known views of a west ledge, generally known as the Red Lode. That there is a well defined west ledge, was established by a suit some years ago, and it now looks as if more suits will before long be brought which will set the question forever at rest. Well informed Comstock miners are outspoken in their belief that several of the Comstock mines have been and are still taking out and milling ore belonging to mines on the Red Lode. Their workings to the west have been made in more or less of a zig zag course to mystify or deceive, perhaps both. Some day there will be a reckoning, and stockholders as usual will have to foot the bill.

Points are out for another break in prices. The break, it is claimed, will be from 40 to 60 per cent from top prices when it sets in. It is said that before breaking prices ought to go some higher so as to sell stock to uncover margin.

From the Comstock mines, uniformly good news comes to hand. In Con. Virginia they are uncovering to the west good to high-grade ore on several levels. In Gould and Curry they have progressed so far in uncovering ore going from \$30 to \$80 a ton, that it is in contemplation to commence milling at an early day in next month. In Best and Belcher the work is westward to strike the continuation of the ore found in Con. Virginia. In Ophir and the mines lying to the north important work is under way. In Savage and also in Hale and Norcross the work if done in the north end mines, would lead to the milling of rich ore and to the paying of dividends. Perhaps public opinion backing the suits now in court, may yet force the managers to "come to time" and work in the interest of all stockholders. From Chollar, Potosi and Bullion there is nothing new to report, and probably there will not be until outsiders have given up their lines of stocks. The same remarks would seemingly cover the situation in the Gold Hill mine, with probably the exception of Overman. The managers of the latter mine appear to be trying to do right by stockholders. They give mine and battery assays, and also more information regarding the work being done in the mine, than do the other companies.

The mining share market opened this (Thursday) morning active and fairly strong. After regular call they were slightly weaker, but under strong buying orders for Overman the market advanced and closed higher, particularly for the Gold Hills. The advance in Overman is due to a report that the assays are higher.

NEWSPAPER AGENTS WANTED.

Extra inducements will be offered for a few active canvassers who will give their whole attention (for a while at least) to soliciting subscriptions and advertisements for this journal and other first-class popular newspapers. Apply soon, or address this office, giving address, age, experience and reference. Special inducements to old agents.

DEWEY & Co., Publishers,
No. 220 Market St., S. F.

A new smelter is to be erected at Gregory, Dakota, to treat ore from the Silver city district.

ASTRONOMICAL SOCIETY.—By the courtesy of the Trustees of the California Academy of Sciences, all the San Francisco meetings of the Astronomical Society of the Pacific, during the next year, will be held in the lecture hall of the Academy's new building, 819 Market street. The annual meeting will be held Saturday at 8 o'clock P. M., and will be open to the public. The annual election of a Board of Directors and Committee on Publications will be held from 8:15 to 9 P. M. The following papers will be presented: "The Fireball in Raphael's 'Madonna di Foligno,'" by Prof. H. A. Newton, Yale University; "On the Similarity of Certain Orbits in the Zone of Asteroids" (second paper), by Prof. Kirkwood, Riverside; "Astronomical Observations in 1890," by Torvald Kohl, Denmark; address of retiring President of the society, by Prof. Holden, Mount Hamilton; "A Few Hints to Beginners in Solar Observations," by Miss E. Brown of England; "Lunar Work for Amateurs," by Thomas Gwyn Elger, F. R. A. S., of England; "The Total Solar Eclipse of January, 1899," by Prof. H. S. Pritchett, Washington University, St. Louis.

GRAVEL IN THE EXTENSION. A Downville dispatch dated March 24 says: "The people of Sierra county are jubilant at the discovery of gravel in the Bald Mountain Extension mine, about five or six miles from here. This find is over a mile from the mouth of the tunnel, and proves the existence of an extensive channel for miles up the Placerville ridge between Forest City and the Gold Lake country. At the Wide Awake mine near here rich gravel has just been found, and these two mines will benefit the entire county."

The combined cannery companies at the Karluk river, Alaska, have arranged for the establishment of a batobery for salmon during the coming season.

Assessment Notices.

CRESCENT MILL & MINING COMPANY.—Location of principal place of business, San Francisco, California. Location of works, Crescent Mill, Plumas County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on Friday, the 20th day of February, 1891, an assessment (No. 5) of Twenty-five cents (25c) per share was levied upon the Capital Stock of the Corporation, payable immediately in United States gold coin to the Secretary, at the office of the Company, No. 310 Pine Street, Room 40, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 6th day of April, 1891, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on MONDAY, the 4th day of May, 1891, to pay the delinquent assessment, together with the costs of advertising and expenses of sale.

By order of the Board of Directors,
J. H. ISHAM, Secretary,
Office, No. 310 Pine Street, Room 40, San Francisco, California.

DELINQUENT SALE NOTICE.

GRAY EAGLE MINING COMPANY.—Location of principal place of business, San Francisco, California. Location of works, Placer county, California. Notice—There are delinquent upon the following described stock, on account of Assessment (No. 22) levied on the 4th day of February, 1891, the several amounts set opposite the names of the respective shareholders, as follows:

Name.	No. Cert.	No. Shares.	Amt.
Barrows, A. W., Trustee.....	555	271	\$ 8 13
Francie, H. L., Trustee.....	444	1,500	45 00
Horton, T. B., Trustee.....	585	2,500	75 00
Lane, Mrs. Sarah, Trustee.....	365	200	6 00
Stout, C. S., Trustee.....	477	953	28 50
Searles, W. A., Trustee.....	518	1,000	30 00

And in accordance with law, and an order of the Board of Directors, made on the 4th day of February, 1891, so many shares of each parcel of such stock as may be necessary, will be sold at public auction, at the office of the Company, Room 11, No. 303 California street, San Francisco, California, on MONDAY, the 30th day of March, 1891, at the hour of one (1) o'clock P. M. of said day, to pay said delinquent assessment thereon, together with costs of advertising and expenses of the sale.

A. W. BARROWS, Secretary pro tem.
Office, Room 11, No. 303 California street, San Francisco, California.

Complimentary Samples.

Persons receiving this paper marked are requested to examine its contents, terms of subscription, and give it their own patronage, and, as far as practicable, aid in circulating the journal, and making its value more widely known to others, and extending its influence in the cause it faithfully serves. Subscription rate, \$3.00 a year. Extra copies mailed for 10 cents, if ordered soon enough. If already a subscriber, please show the paper to others.

Don't Fail to Write.

Should this paper be received by any subscriber who does not want it, or beyond the time he intends to pay for it, let him not fail to write us direct to stop it. A postal card (costing one cent only) will suffice. We will not knowingly send the paper to any one who does not wish it, but if it is continued, through the failure of the subscriber to notify us to discontinue it, or some irresponsible party requested to stop it, we shall positively demand payment for the time it is sent. LOOK CAREFULLY AT THE LABEL ON YOUR PAPER.

A LIBRARY FOR \$1.00

Five books in one. Worth its weight in gold to every mechanic. The very latest information for 20 different trades. This wonderful book contains 575 pages absolutely teeming with rules, tables, secret processes, and new information that cannot be had elsewhere for less than \$25.00. The Model Steam Engine—How to Read an Indicator—The Westinghouse Air Brake—Blacksmith's and Machinist's Tools—Practical Mathematics Simplified—Tin and Sheet Iron Worker's Manual—Carpenter's Manual—Points for Painters—Magnetism and Electricity—How to Get a Patent—A Mechanical Dictionary. Everything fully explained in one handsome volume and guaranteed to be absolutely correct. Send \$1.00 for a copy bound in silk cloth, or \$1.50 for Morocco binding. With each copy of the book we give free a complete working chart for setting gear teeth. The regular price of this chart is \$1.50. **AGENTS WANTED.** Write for terms. **LAIKD & LEE, Publishers, 263 Wabash Ave., Chicago, Ill.**

The Explorers' and Assayers' Companion.

A Third Edition of selected portions of the "Explorers', Miners', and Metallurgists' Companion."

A practical exposition of the various departments of Geology, Exploration, Mining, Engineering, Assaying, and Metallurgy. Price, \$8.00 post-paid. Sold by DEWEY & CO., Publishers, 220 Market St., San Francisco.

By J. S. PHILLIPS, M. E. The work is divided into four parts—Rocks, Veins, Testing and Assaying. The geological chapters are intended to give miners a practical idea of the various formations. The chapters on mineral veins are derived from long observation, and the section on exploration has been carefully considered. All that relates to discrimination and assay of minerals has been kept as free from formulae as possible. The work is written for practical men, and all the explanations and descriptions are clear and to the point. It is so prepared that it is useful to uneducated men as well as scientists.

Books on Working Ores.

By GUIDO KUSTEL, M. E.

ROASTING OF GOLD AND SILVER ORES (Second Edition) and the Extraction of their Respective Metals without Quicksilver. By GUIDO KUSTEL, M. E. 1890.

This rare book on the treatment of gold and silver ore without quicksilver is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe, and the why and wherefore. It contains 156 pages, embracing illustrations of furnaces, supplements and working apparatus. It is a work of great merit, by an author whose reputation is unsurpassed in his specialty. Price, \$3, coin, postage free. Sold by DEWEY & CO., Publishers, 220 Market St., San Francisco, Cal.

By C. H. AARON.

AARON'S LEACHING GOLD AND SILVER ORES, the most complete hand-book on the subject extant, 164 pages octavo. Illustrated by 12 lithographic engravings and four wood cuts. Fully indexed. Plainly written for practical men. In cloth, \$3. Sold by DEWEY & CO., S. F.

THE PELTON WATER WHEEL

GIVES THE HIGHEST EFFICIENCY OF ANY WHEEL IN THE WORLD. OVER 1300 IN USE.

Affords the most simple and reliable power for all mining and manufacturing machinery. Adapted to heads running from 20 up to 2000 or more feet. From 20 to 30 per cent better results guaranteed than can be produced from any other wheel in the country.

ELECTRIC TRANSMISSION.

The advantages the Pelton Wheel affords in the way of a uniform and reliable power, close regulation, and the facility of adaptation to varying conditions of speed and pressure, have brought it into special prominence and extensive use for this class of work.

All applications should state amount and head of water, power required and for what purpose, with approximate length of pipe line. SEND FOR CATALOGUE.

THE PELTON WATER WHEEL CO.

121-123 MAIN STREET, SAN FRANCISCO, CAL., U. S. A.

PELTON WATER MOTORS, Varying from the fraction of 1 up to 15 and 20-horse power, unequalled for all light-running machinery. Warranted to develop a given amount of power with one-half the water required by any other. SEND FOR MOTOR CIRCULAR. Address as above.

THE GATES ORE AND ROCK BREAKER.

UNLIMITED IN CAPACITY, UNEQUALED IN EFFICIENCY, UPWARD OF 3000 NOW IN USE.

Will do more than twice the work of any other with the same cost in wear.

Gives a fineness of product that increases the capacity of any mill from 25 to 40 per cent without any additional expense. THE BEST AND ONLY CRUSHER ADAPTED TO MACADAM ROAD WORK. Send for Circular.

THE PELTON WATER WHEEL CO., 121-123 Main Street, San Francisco, General Western Agents.

DIXON'S SECRETARY No 2 75
DIXON'S Lead Pencils
DIXON'S Stove Polish
DIXON'S Crucibles.
DIXON'S GRAPHITE PAINT. For all Iron and Wood Work. Covers twice the surface of any other paint.
SOLD BY ALL DEALERS.
J. G. ALLEN, Agent, 304 Market Street, San Francisco, Cal.

Sold by all Stationers

DIXON'S Axle Grease

"Fault Scarps."

Salt Lake City is built just south of a spur which projects four or five miles westward from the front of the Wasatch. This spur is separated from the mountain mass by a fanit plane along which the Wasatch block has, relatively speaking, risen, and it is separated from the valley on the remaining three sides by a curved fault plane along which the block underlying the valley has, relatively speaking, fallen. The first of these faults was determined from the rock structure by Prof. J. E. Clayton, of Salt Lake City. It is also indicated at its northern end by a fault scarp which can be traced for a short distance up the groin. The fault on the side of the valley is exhibited at the west and northwest by a series of scarps, which begin in the northern suburbs of Salt Lake City near Warm Springs. The surface of the plane below is thrown by the same faulting into irregular waves and at one point it is distinctly terraced. On one of the faulted benches an ore-reducing establishment has been built, using the lower bench as a dumping ground for its slag. Between the point and the hot spring an alluvial cone built against the face of the spur is traversed by a typical scarp, which has been sketched by Mr. Holmes and figured the

ROCK BREAKER FOR FINE CRUSHING.—See page 216.

"Lake Bonneville" of Gilbert of the United States Geological Survey.

The sketch is herewith reproduced, where may be seen not only the scarp but its relation to other elements of the local geological history. The face of the spur consists of a

paleozoic limestone, inclined at various high angles. The horizontal terraces it bears are shore marks of the ancient lake.

The portion of the alluvial cone that lies above the fanit scarp is channeled by a stream, and a study of the system of terraces bordering

this channel shows that the total displacement of 30 feet was produced by at least three independent movements, the measures of the parts being 15 feet, 5 feet and 10 feet. At this point and elsewhere in the vicinity the scarp is utilized by the burners of lime, who construct these kilns against its face and use the terraces above and below for the two approaches needed in the management of the kilns. The proprietor of the kiln represented in the plate enjoys the further convenience of quarrying his limestone from the adjacent cliff.

The hot spring at the apex of the spur is on the line of the fault, and a scarp can be traced from it in either direction. The powder-houses standing a little farther northward are partly above and partly below the fault scarp. Many of the fault features of this vicinity, including those figured in the plate, may be seen from the car windows of trains passing between Salt Lake City and Ogden.

THE mines of Butte and Anaconda are having serious trouble with the Montana Union R. R., growing out of the transportation rates for hauling ore, fuel and supplies. The furnaces at the Anaconda have been shut down, and it looks as if it might take several months to settle the difficulty.

WE received at this port, during the past week, 42,000 tons of coal.

FAULT SCARP CROSSING ALLUVIAL CONE, NEAR SALT LAKE CITY.

CORRESPONDENCE.

We admit, undorsed, opinions of correspondents.—Eds.

Reno, Nevada and Vicinity.

EDITORS PRESS:—During a recent visit to Reno, I gleaned a few facts from some of her citizens that may be worthy of notice. While not the metropolis of Nevada, being outranked in both age and population by Virginia City, it is generally conceded to have more elements of substantial prosperity than any other town in the State. It is pleasantly situated on the Truckee river at the northwestern edge of the famous Truckee meadows, a fertile and productive basin, moderately estimated at 225,000 acres of arable soil. Four-fifths of this extent, it is safe to assert, is devoted to pasturage and the production of hay. Though all kinds of cereals, vegetables and hardy fruits are congenial, no attempt has scarcely been made to produce them for export, it having generally been considered less remunerative than hay, which has usually found a ready sale at a high price. For hundreds of miles north, east and south of here, beef cattle are annually collected at this point and fed during winter months on the alfalfa hay of the meadows, and shipped as required to the California market.

At this place reside a number of the prominent stockmen of the State, the town affording ample educational and social advantages for families. Geo. W. Mapes, who bears the distinction of being the Cattle King of Nevada, and owning large herds in Northern California and Oregon as well, is one of the public-spirited men of the place. Shespe as well as cattle owners rejoice over their success during the past year. While the year 89-90 proved the most ruinous in the loss of live stock since the country was occupied by white men, the last winter was about the lightest ever known. All stockmen I met reported alike: "No loss this year, and still in nearly as good condition as in the fall."

The Riverside Flour Mill of Reno bears a good reputation for the quality of its manufacture. Its capacity is 100 hhls. per day. From Mr. H. H. Beck, the superintendent I learned to my surprise that Washoe county produced for market only 350 tons of wheat last year. This gentleman has made a close calculation (and from his long and intimate acquaintance with the country his estimate should be reliable) and aims up that the Truckee Basin is capable of furnishing breadstuff for the entire State. At present the Riverside Mill gets most of her grain from Californians, a small proportion coming from the Lovelock settlement on the Humboldt and from Honey Lake, also from Salt Lake Valley. It is Mr. Beck's opinion that farmers here would enhance their gains to devote more attention to wheat-growing as they would almost find here a ready home cash market at \$8 per ton more than their California neighbors—that being the cost of importing grain by S. P. R. R. Reno has been unfortunately in losses sustained by fires from time to time, Riverside mill being the fifth and only mill now standing. The fire of two years ago has still left its mark, though the district has been partially rebuilt with substantial brick houses. Two causes seem to conspire in effectually preventing Reno from making the advancement which her position and other elements of prosperity would promise. Business men claim that the S. P. R. R. Co. have discriminated against Reno on freight charges, very materially for years, out of spite for having been compelled to pay their taxes to Washoe county. Another cause why capital and population seek other fields is said to be the high taxation imposed in Nevada in order to enjoy the luxury of a State government.

Reno has good transportation facilities, the overland S. P. R. R. from east to west, the V. & T. leading south and the N. O. C. R. R. north. The Truckee river affords an unailing supply of the finest water for every use, including mill power and for irrigation. A number of enterprising men here are investing capital for the advancement of irrigation schemes on a large scale. The town has a population of 4000. Its altitude is 4500 feet. For healthfulness it has very few rivals. Its claims in this respect are recognized substantially in different ways, one of which is in having established the best schools, both public and private, in the State, including the State University. I had the pleasure of visiting this institution, of which Prof. S. A. Jones is the president. It was established at Elko in '77 and removed to Reno in '83. The attendance is reported on the increase, there being 60 students at present and ten instructors.

The various secret and benevolent Orders and choroeas appear to be well represented. The streets are lighted at night by electricity, and there is apparently an air of thrift and comfort about most of the homes, notwithstanding the mormor of dull times is occasionally heard.

Adjoining the asylum, you are confronted with a species of political jobbery which was put through the Legislature in '83. The stone walls for a penitentiary, in a useless and a half-completed state, mock the honest taxpayers who were jilted out of \$100,000. It is still believed, however, that the penitentiary will eventually be voted here from Carson City, and that in such case the present waste will not be all a waste.

F. B. L.

California School Lands.

EDITORS PRESS:—It seems that the State has various tracts of school lands for sale; is there no law or authority for advertising them, giving the location, description section, township, etc. As it is now, if a person desires to purchase a tract of school land, he is compelled to pay some land shark or land attorney a high price just to tell him where such land is located, which information he has secured from the State land office. I am informed that land companies send parties out to survey, photograph and locate the more choice tracts of land, and then hold the land for high commission for the information secured. I suppose they have the right to do this, but it seems that the State might spend some of the tax payers' money in giving notice to the public where these lands are located, as well as to appropriate money for portraits, of each succeeding Governor of this State, that the masses of the people never see and have no use for.

San Jose.

W. T. EDDY,

EDITORS PRESS:—There is no law authorizing the advertising of school lands. Each and every citizen of the State can get as full and complete information at the land or surveyor's office, Sacramento, regarding the lands, as is possessed by the officials in charge. Locations and surveys, together with field notes, can be had of lands which are not sold or filed on; but even with this knowledge, unless the would-be purchaser goes in person or sends a responsible agent to examine the land, he takes great chances in getting that which is not to his liking. Of necessity, to obtain personal knowledge or information through a trusted agent takes time and costs money. Aside from this, while securing or waiting for desired knowledge regarding the land, it is liable to be filed on by another person. It is the cost of getting this information, through trusted agents, that we are informed school land agents charge to purchasers, when either locating or selling these school lands.

The writer's canvass among those who have sold, and also those who have bought school lands, has resulted in giving him much valuable information, which briefly stated is as follows: The school lands were set apart by the United States to the State, for the benefit of the public schools, the proceeds received from their sale by the State going to the school fund. They comprise the 16th and 36th sections of each township, or the lands selected by the State in lieu. These lands are sold in tracts of from 40 to 640 acres. Residence on, or improvement of, the land is not necessarily required. The title to school lands comes from the State direct to the purchaser, and is based on patent to the State from the United States. The terms of payment are much easier than on any other cheap lands offered.

The school lands are well culled, yet it is said that in some of the northern counties good sections of rolling and plateau lands can be found, and as the localities are settled up, better railroad and shipping facilities are among the possibilities within the next five years. It is said that some prairie lands are offered in the southern part of the State. These lands have heretofore been classed as arid, but under our irrigation system and developments made in the various counties where located, they have fully demonstrated their productiveness. Railroad construction is very active in this part of the State. In the coast and central counties, it is said that there are to be had some choice hill and mountain lands. Many of the most flourishing and best paying hill or mountain orchards were at one time uninviting chaparral-covered lands.

Aside from farming lands there are timber lands, for which, owing to their growing scarcity, there is an increasing inquiry. This demand is probably intensified by reason of the last Congress passing a law withdrawing Government timber land from market.

In connection with the above, the following from ex Governor R. W. Waterman's message to the 28th Legislature of this State is of interest: "While California has been selling her school lands at an absurdly low price, Michigan has been realizing over \$5 per acre; Indiana, about \$4 per acre; Illinois, about \$4 per acre; Ohio, over \$5.50 per acre; Colorado, from \$3 to \$50 per acre; Nebraska, not less than \$7 per acre, for land obtained under the same grant, while in Minnesota \$5 per acre is the minimum price, and she has sold 1,000,000 acres of her school lands at an average of \$6 per acre. In Kansas, school lands are sold after appraisement, the minimum price being \$3 per acre.

"Immigration is large, lands are rapidly increasing in value, and Section 3494 of the Political Code should be so amended that our remaining school lands be sold for a price commensurate with their value, made subservient to the purpose for which they were donated, and legislation enacted from the standpoint of finance—revenue being their sole object."

J. R. F.

The Death Valley Find.

EDITORS PRESS:—A man named Montgomery who has been for the past three months prospecting in Death Valley, has departed for San Francisco with a valise full of the finest specimens that could be seen. They are from a new find 20 miles west by north from Winters' ranch Death Valley, Nevada. It is said that a large ledge 12 feet thick located along the line for some eight miles has been found, and that the quartz at the point where the specimens came from is literally hung together with gold. It excited a certain class of people

of this place (Daggett) and of Osioo and many teams with prospecting parties have left for the new find. Since that, other parties from San Francisco have arrived here and three more teams have left with still more to go. Four men are now said to be standing guard over three of the locations. There is said to be timber and water in plenty for quartz milling purposes. They have great hopes that this is at last the famous Breyfogle or Lost mine for which many people have hunted for years. They say that the ledge has opened in 20 places and has really been known for a month, but they have kept quiet about the find. It is expected that a great rush of "solitaries" will flock in now when it is too late to get anything; and that bee-hunters and pumpkin rollers will expect to get rich right off. This find is at a distance of 150 miles from here on the Atlantic and Pacific road, but I give you this account as reliable as I could get it.

S. P. BLADE.

Daggett San Bernardino Co.

The Duty on Coal.

Alfred Bannister, the vice-president and general manager of the Starr Milling Company of this city, has written a brief "suggestion" for the benefit of California farmers and millers, which will be presented to the Produce Exchange and the Chamber of Commerce. He declares that our farmers now labor under the disadvantage that our population is too small to consume sufficient imports to bring here the tonnage required for the export to Europe of the wheat surplus. Mr. Bannister's suggestion is as follows:

"That the State of California should refund to all importers of coal from Europe and the Australian colonies the import duty of 75 cents per ton at present charged.

"It is not proposed to make this refund on coal from British Columbia, which is brought here in vessels chartered for the export of wheat hence to Europe.

"Coal being bulky and of great weight compared to its moderate value financially, already brings more tonnage fit for exportation of wheat to our coast than all other imports combined. The adoption of the above suggestion would as surely bring us considerably more tonnage than now to export our wheat, as this increase of tonnage would reduce wheat freights hence to Europe. This reduction of freights would enable shippers to pay more than now by \$1 to \$2 per ton for wheat to farmers, who would also be further benefited by the greater value given to their land through this increasing its earning power.

"No doubt this proposed action would slightly prejudice our few coal producers, but it would, without doubt, very considerably benefit (1) our most deserving 50,000 farmers; (2) our steamship, railroad and gas companies; (3) our growing home industries, and (4) every householder and consumer of coal."

Mr. Bannister declares that neither his company nor himself ever import coal, so that his sole motive in making his suggestion is the welfare of the State and of its farmers.

Treasury Regulation About Ores.

Attention has been called to the probability of certain frauds being perpetrated in imports of lead ore to this port. There was reason to believe that the foreign shippers in some instances endeavored to smuggle lead into this port by capping the sacks with a covering of silver ore upon which there is no duty. The Acting Secretary of the Treasury, A. B. Nettleton, has covered certain phases of the fraud in a circular received at the collector's office. It recites that Article 9 of the Department Circular No. 4 of January 8, 1891, relative to the smelting and refining of imported ores and crude metals in bond, has been amended as follows:

"In case the operation of smelting and refining cannot be carried on in a single establishment, the bonded warehouse shall be designated as a smelting warehouse, and the unrefined products or hulkion obtained from the smelting of crude metals or ores in such warehouse may be removed therefrom for shipment to any refining works upon the payment of the duties on the quantity of crude metal or ore contained in the imported mass used in the smelting, or upon the production of a certificate from a collector of customs at a seahoard port, stating that a quantity of dutiable refined metal equal to 90 per cent of the quantity indicated by the original assay has been actually exported by the owners of the bonded smelting warehouse or their agents, and that the metal so exported was shown by evidence satisfactory to the collector to have been produced in their bonded warehouse, wholly or in part from imported ore or crude metal."

MUCH MORE BULLION.—The production of gold in the United States, according to the official estimate of the United States Mint, is \$64,000,000 for 1889 and 1890. Besides this, not less than \$1,000,000 of foreign gold coin is brought into this country by foreign immigrants, which is not taken into any official statistics of imports. The total net exports of gold for two years amount to \$41,584,000. From these figures it will be seen that, unless the official statistics of the Government are entirely worthless, there has been an increase of gold in the form of bullion or coin to the approximate amount of \$23,500,000 in the last two years.

Treatment of Iron-Coated Gold.

A writer in the *Anstralian Mining Standard* in speaking of the Pambula gold-fields, has the following to say:

This comparatively new gold-field is rapidly coming to the front, recent developments tending to show that these mines will prove very valuable. The way in which the precious metal has been deposited in the lodes is in a measure unique, and it is beyond a doubt that the ordinary methods will fall to solve the extremely finely divided gold these lodes contain. Several parcels of ore have been treated in Sydney by the method of wet crushing and amalgamation, the yield of gold fully proving the richness of the ore, though the loss of gold in that method of treatment is large, especially in the poorer sorts, in which it is estimated that 30 to 70 per cent is lost. This great loss arises from two causes: First, from the very finely divided state of the gold, which is known as "float" or "float" gold; the second is from the fact that, like some of the gold in the Mt. Morgan ore, it is coated with a film of iron which prevents the gold coming into contact with the quicksilver, and if not saved in the concentrates, it is lost in the tailings. It is known that if tailings contain 5 dwt of free gold to the ton, the gold can be seen with a moderately powerful glass; but if coated as above, its presence cannot be detected even in very rich concentrates. Recently a parcel of some ten tons of rich stone from Pambula was treated by wet crushing and amalgamation, the operation being performed in Sydney with great care. The result, we are informed, was 164 oz. 2 dwt. of retorted gold; the concentrates weighed 256 lbs., which assayed at the rate of 186 oz. to the ton, representing a money value of about £785 per ton of concentrates, or £9 per ton of ore. Notwithstanding the rich character of these concentrates, the gold they contained was not visible under a powerful glass, thus showing that the gold was concealed by a film of iron.

The tailings assayed 3 oz. 18 dwt of fine gold, say £16 in money value per ton of tailings. To recapitulate: The value of gold saved per ton of ore is, say, £60; value of gold in concentrates, £9 per ton of ore; value of gold in the waste, £16 per ton of ore. Thus the total of gold in concentrates and tailings is about £25 per ton, or, in round numbers, £250 worth of gold in the 10 tons referred to, which could not be saved by the ordinary process. Dry crushing and obloration will and has saved 96 to 98 per cent of all the gold in the ore. A parcel of two tons of ore from another lode at Pambula was recently received in Sydney. One ton was treated by wet crushing and amalgamation; the other ton by obloration. The assay value of the ore was under 2 oz. per ton. There was no choice between the two lots. That by obloration resulted in saving 97½ per cent of the gold. It was dry crushed, and when placed in the air-tight cylinders, there was no chance for any of the gold to escape. Compared with the other method, obloration secured three times more than was saved by wet crushing and amalgamation. Bearing on the question of iron-coated gold, and on the fact that it will not in that condition amalgamate with quicksilver, we publish the following extract from the report of a lecture by Dr. Leihus, assayer to the Mint, on the occurrence of a similar difficulty with regard to Queensland ore:

Having now shortly described the remarkable occurrence and purity of this Mt. Morgan gold, a not less interesting though less satisfactory fact is this—that only about half the gold is extracted by the ordinary quartz crushing and amalgamating machinery. Having the small quartz-crushing machinery erected at the Sydney Mint under my charge, I have had an opportunity of testing this fact. We received, through Mr. Hall of Sidney 458 lbs. of this ferruginous quartz, part of it consisting of pitted stone. It was carefully crushed and amalgamated in the Chilian mill, with 240 lbs. of mercury. Thus seven 44-100 oz. of gold, assaying 991.5 were extracted. Another lot weighing 174 lbs. was similarly treated, and 12 12-100 oz. of gold extracted, assaying 998.2. Thus Lot 1 gave gold at the rate of 39 32-100 ozs. standard per ton of quartz. In Lot 1 gold at the rate of 46 ozs. 2 dwt. 12 grs. per ton was left in the tailings; while in Lot 2 the tailings assayed 64 ozs. 5 dwt. 18 grs. of gold per ton. Both lots of tailings were now mixed and passed for two hours in the Chilian mill with 240 lbs. clean retorted mercury—only 13 ozs. of gold assaying .981 were, however, obtained by this treatment. The tailings were dried and found to weigh 476 lbs., containing gold at the rate of 41 ozs. 13 dwt. 16 grs. per ton; or in above 476 lbs. tailings no less than 8 ozs. 17 dwt. 3 grs. gold. I have brought some of the tailings here. Under the microscope there is no gold visible. That the ordinary amalgamating Chilian mill did not extract all the gold in this stone I can only attribute to the supposition that the oxide of iron has literally coated some of the fine gold, thus preventing it from coming in contact with the mercury. For another ore, Plattner's chlorination process, if worked on a large scale, ought to be highly successful. I am glad to bear that arrangements have been made by which the tailings will presently be treated at the mine by the chlorination process, whereby the gold is dissolved by an aqueous solution of chlorine gas, and precipitated by hydro-sulphuric acid.

Hydraulic Mining.

Unity of Action Demanded.

Alf Trudger, a prominent miner of Nevada county, writes to the *Nevada Transcript* as follows:

I have been a constant reader of your paper for the last seven years, during which time I have often read therein articles on farming and hydraulic mining; and often have I seen whole columns copied from the representative valley papers most unfavorable to that branch of the mining industry; and I am sorry to say that from the tone of the *Sacramento Bee* and the *Marysville Appeal's* articles (which papers are undoubtedly the mouthpieces of the Anti-Dam Association), the miner is looked upon as anything but the generous, whole-souled being that he really is. Poor fellow! How fortunate he was born a gaudier, when so many who subsist on his labors are so anxious to "kill the goose that lays the golden egg." I wonder if it ever occurred to our valley friends to go back to first principles and ask themselves how it was that our glorious country achieved her independence? To such question there is but one answer—by unity! The farmers are united. So were the soldiers in the days of yore; but while they did the fighting, others supplied the wherewith to clothe, to feed. If they all had not taken an interest in national affairs, where would our country have been to-day? And while the vocation of one was to protect, the ambition of the other was to keep alive the protector. How matters have changed. No sooner is it known that you are a benefactor than envy becomes rampant and will not be satisfied until your very existence is "wiped out." Such has been the fate of hydraulic mining. Here is the former waging war against the miner to the detriment of both. What does the farmer work for? Gold. What does the miner work for? Gold. Then why not let them unite and obtain it? If it is not done in our generation, it will be in the next, and if we do not embrace the opportunity, we have ourselves to blame for it. In Nevada county alone, there are hundreds of millions in gold known to exist in the gravel deposits that have been already discovered and thoroughly tested.

In the United States Treasury at Washington there are hundreds of millions lying idle that have been extracted by the miner and turned into specie. Why not let a little of that which is lying idle be appropriated to the good cause of obtaining more, especially when you know exactly where to get it from? Do you not think that it is a disgrace to the present state of so-called advanced civilization that localities where so much gold is known to exist are permitted to lie idle, and the gold to remain there without any attempt being made to extract it? Do you not think there are brains enough on the Pacific Coast to devise a means and carry it into execution if the wherewith were forthcoming whereby this gold could be extracted from the gravel without injury to the farmer? Do you not think that if the miner and the farmer became a "unit," both realizing the vast benefit that they would each derive, from the fact that so much more gold was to be put in circulation for the avowed purpose of producing more, that they could prevail upon their representatives in the Legislature to unanimously vote in favor of a liberal appropriation from the National Treasury? Do you not think that all the States and Territories on the Pacific Coast would assist California and so instruct their representatives to the national capitol? Then with a unanimous voice from the Pacific Coast, could not an appropriation be obtained from Washington? What is money? Is it not mineral? How came it to be locked up in the Treasury vaults at Washington? It gradually accumulated there, but it came first of all from the mines. The majority of the gold is from California and the silver from Nevada, Arizona and Utah, and the more of it the miner produces the more is the real value of the United States enhanced. No matter what business you are engaged in, aside from mining, the basis of it is the gold and silver that have been produced by the miner, and the miner of to-day who produces more is a universal benefactor, an honor to the State and a blessing to the community. We live in a land where there is unlimited gold. The pioneers have but shown us where to dig for it and the native and adopted sons should not be slow in extracting it. All those who are not workers in the field should at least encourage those who are, and do all in their power to assist in uncovering the gold that lies under our feet and placing it on the surface for the benefit of mankind. The necessary appropriation being once obtained to use it to advantage would be a secondary consideration. Efficient dams could be placed at the mouths of those rivers which empty into the Sacramento river. A flume sufficiently large could be so constructed as to enable dredgers to elevate the alluvium from behind the dams into the flume and carry it down on to the tilled lands, and so make farms. This flume could be constructed with rifles in the bottom and be cleaned up occasionally. Considerable gold would be found there. All mining companies which availed themselves of these improvements would be only too willing to pay a per centage to keep the dredgers and the flume in repair. Only if it is executed at all, let it be done on a large scale. If two dredgers won't keep away the silt, one put on twenty so all the mines can work. That is progression. It may cost considerable money, but then the money is not being buried, it is

merely circulating. The object of the circulation is future production. In California, we ought to produce \$50,000,000 in gold annually, and that can be achieved in time if we but go back to first principles—unity—and live up to them.

State Appropriations for the Fair.

Bills have been presented in the Legislature of the various States and Territories as follows, for appropriation to the World's Fair at Chicago:

Alabama	\$30,000
California	300,000
Connecticut	25,000
Colorado	150,000
Idaho	20,000
Illinois	1,000,000
Indiana	75,000
Iowa	50,000
Kansas	50,000
Maine	40,000
Massachusetts	75,000
Minnesota	100,000
Missouri	100,000
Montana	100,000
Nebraska	150,000
Nevada	20,000
New Jersey	20,000
New York	250,000
North Carolina	25,000
North Dakota	25,000
Ohio	100,000
Oregon	100,000
Pennsylvania	300,000
Texas	300,000
Vermont	5,000
Washington	240,000
West Virginia	40,000
Wisconsin	250,000
Wyoming	30,000
New Mexico	25,000
Oklahoma	7,000
Total	\$4,002,000

Bills have been introduced in the following Legislatures and entirely failed:

Arkansas	\$100,000
South Dakota	25,000

Total. \$125,000

Both houses in these two States voted against the bills and refused any appropriations.

In the following States the World's Fair appropriation bills have been passed by both houses of their Legislatures and been signed by the Governors and are in force:

California	\$300,000
Idaho	25,000
Indiana	75,000
Iowa	50,000
Montana	100,000
New Mexico	25,000
North Carolina	25,000
Oklahoma	7,000
Oregon	100,000
Pennsylvania	150,000
Vermont	5,000
Washington	100,000
West Virginia	50,000
Total	\$1,007,000

HUGE CHUNKS OF METAL.—When excavations were made recently for the foundation of the 20 story Masonic Temple, which is rapidly going up at the corner of State and Randolph streets in Chicago, an 18-ton mass of iron, copper and other metals was discovered. A wholesale hardware store stood on the lot at the time of the great conflagration of 1871, and this mass of iron represents a portion of the stock which was melted by the intense heat and precipitated into the sub-basement. It will be exhibited at the World's Columbian Exposition by D. A. Stout, The Copper Queen Company, at Bisbee, A. T., will exhibit at the fair a mammoth specimen of ore from their mines. The work of chiseling the piece out has been going on for some time, and great care is being taken in its extraction. It is estimated that when ready for shipment it will weigh five tons and will be in the shape of a brick. The specimen is from the big stoep from which such beautiful specimens have been taken, and will contain about every known character of copper formations and colorings. It will, without doubt, be the most attractive specimen on exhibition.

NEW GOLD FIELDS.—George Ladd arrived in Winnemucca this morning from the new gold fields northeast from Disaster Peak. Mr. Ladd left Lovelocks some time in the forepart of February and has been prospecting on Kluge River and Horse Creek ever since. He brought in a small vial of fine-looking gold, some scales weighing as much as 50 cents. He claims that the ground on Horse Creek, where they sunk their shaft, will yield from one cent to 50 cents to the pan. In one pan they obtained as high as 75 cents. Ladd should be a very good judge of the weight of gold, as he has been in the neighborhood of the Spring Valley mines for years, and has carried probably \$100,000 or more from those mines to Lovelocks for the Chinamen. He is in after lumber for sluiceways and other material and provisions. There are four of them in the company, the balance remaining at the find until Mr. Ladd returns. It has been known for years that the King River country contained gold, but until recently there has been no excitement about them.—*Silver State (Nev.)*

A TIN-PLATE MILL.—The St. Louis Stamp Company has inaugurated the actual work of erecting the first tin-plate works in this country, near their present rolling-mills. The iron now used by the company in the manufacture of plates comes from Tennessee, but it is proposed to establish a mammoth steel-mill and iron foundry just north of Madison, Ill., to turn out all the sheets used in the manufacture of tin plate.

Ramie Culture.

A French professor expresses great confidence in the future of ramie culture in France. He thinks it will be the means of delivering that country from its present heavy obligations to other countries for textile materials. Whatever we of California may think of these conclusions, we cannot but note with interest the hopefulness of the ramie industry in a country where both its cultivation and manufacture have made most important progress during the comparatively short time of but little over a single decade.

Commencing with its cultivation only, it soon began to take a prominent place among the manufacturing industries of that thrifty people. Starting without any aid from Government, it soon arrested the attention of government officials to such an extent as to induce them to speak encouraging words for it. Experiments were also ordered for the purpose of ascertaining its relative excellence, as compared with other fibers. One series of these experiments in comparison with Russian hemp showed the breaking weight of same to be from 125 to 150 as compared with 80 for Russian hemp. Another series of experiments made in regard to its traction capacities with hemp, flax, silk and cotton were found to be represented by the figures 100, 36, 25, 13, 12, respectively. The elasticity of the same fibers stood 100, 75, 66, 400, 100. Several other carefully conducted experiments were also made, in all of which, ramie held the first position with large odds in its favor.

A very important property of ramie for the manufacture of oordage and sail cloth was found to exist in its incomparable power for resisting the action of damp atmosphere and water.

There is no fiber known which is capable of being wrought into such a variety of useful fabrics as ramie. Samples have been shown in this city of every class of goods for both male and female wear, from the coarsest and cheapest which can be utilized up to fabrics which bear almost undistinguishable likeness to the best Lyons silk, or such as will not suffer in comparison with the finest Chantilly lace.

Until within a few years manufacturers have been compelled to rely mostly upon the slow and tedious though cheap process of hand decortication, as practiced in India; but recently most effective machine decorticators have come into use which are able to do the work quite as well and cheaper than the same work can be done by the ten-cent-a-day laborers of India. By the aid of these machines there need be no lack of the raw material for our factories wherever or whenever they might be established.

Several of these machines have been introduced into California, one of which was shown at work at the last Mechanics' exhibition in this city, which appears to answer all the demands that can be asked for such work. In all other portions of the world where ramie decortication has been introduced, it has been worked in a state more or less green or damp, and resort has to be made to some chemical process to remove the gummy substance which always adheres to the fiber. It has been found, however, that the dry climate of California so effectually removes the moisture from this gum and renders it so brittle that it is sufficiently removed in the form of fine dust by the action of the decorticator to place the fiber in a marketable condition without the use of chemicals. This is a very great advantage, saves much cost and largely adds to the advantage which the California grower will have over growers in other and less favorable climates.

Considering all these facts, and especially this last-named advantage, it would seem to behoove California farmers to carefully consider the importance of this new and promising industry. Experiments made under the auspices of our State University, as well as by many practical farmers in various portions of the State, have fully shown the admirable adaptability of this State for the cultivation of the ramie.

A bill appropriating \$10,000 for the encouragement of ramie planting in this State has passed both branches of the Legislature—the Senate by a unanimous vote—and will, no doubt, receive the signature of the Governor.

TESTING THE SILVER COINAGE LAW.—The silver-brick matter has been renewed, a petition being filed in the Supreme Court of the District of Columbia in behalf of George G. Merriam and associates, praying for a mandamus on Secretary Foster to compel him to receive the silver bar for free coinage.

ANOTHER RICH STRIKE.—It is reported that a rich strike has been made in the Lakeview mine at Lundy—\$250 gold ore, and lots of it. The Lakeview is one of the syndicate of mines recently sold to Chicago parties, and of which R. T. Pierce is superintendent.—*Bridgeport Chronicle-Union.*

The inventor of the Maxim gun is devoting his attention to flying machines. He makes the somewhat astounding statement that he has obtained one-horse power from a motor weighing only six pounds, and that this will support 135 pounds in the air.

An Improved Fuse-Cap Fastener.

Mr. N. W. Moody of Fresno, Fresno county, Cal., has recently patented a device which is especially designed as an improved implement for fastening the caps on fuse employed in exploding giant powder. The pliers are formed of two similar parts, connected by the pivotal rivet, each part having a cheek with notches, at the sides of which are cutting edges for cutting the fuse. The curved jaws beyond the cheek pieces, when closed, form a circular aperture, around which the jaws are beveled, one jaw having a tongue which fits in a groove in the other jaw. The pliers are employed for contracting the end of the cap on the fuse firmly and absolutely water-tight, thus avoiding the dangerous operation of digging out wet and unexploded loads. Miners who have used implements of this class will appreciate the improvements in the one designed by Mr. Moody. The instrument crimps the cap on the end of the fuse firmly. The fuse-cutter is simple and efficient. This implement is neatly gotten up of the finest cast steel and nickel plated. It is small and light but strong and well adapted for its purpose.

It is well known that numbers of miners are killed annually in the United States and elsewhere while going through the dangerous operation of digging out wet and unexploded loads, to say nothing of those losing an eye or a limb in the same way. Accidents of this nature could be avoided, and the handling of Giant Powder made comparatively safe, by the use of an instrument such as this invented by Mr. Moody. Mining companies would also relieve themselves from the liability of damage suits were the use of such an instrument adopted by them. Another item of interest and benefit to mining companies is the time saved in preparing the cap and fuse for use. Instead of taking time to use soap and a string or tar, after the usual effort to fasten the cap to the fuse, this implement enables the miner to cut the fuse and fasten the cap on firmly, and absolutely water-tight; and this is done in a few seconds, which means no loss of time at all. Any one familiar with blasting operations can appreciate the advantages of this implement.

The New Vagrant Law.

The Senate bill defining vagrancy and punishment has been signed by the Governor. It provides that the following classes of persons shall be deemed vagrants, and when arrested shall be punished for misdemeanor: First—Every person, except a California Indian, without visible means of living, who has the physical ability to work and who does not seek employment nor labor when employment is offered him; or, second, every healthy beggar who solicits alms as a business; or, third, every person who roams about from place to place without any lawful business; or, fourth, every person known to be a pickpocket, thief, burglar or confidence operator, either by his own confession or by his having been convicted of either of said offenses, and having no visible or lawful means of support, when found loitering around any steamboat landing, railroad depot, banking institution, broker's office, place of public amusement, auction-room, store, shop, or crowded thoroughfare, or on omnibus, or at any public gathering or assembly; or, fifth, every idle or dissolute person, or associate of known thieves, who wanders about the streets at unusual hours of the night; or, sixth, every person who lodges in any barn, shed, shop, out-house, vessel, or place other than such as is kept for lodging purposes, without the permission of the owner or party entitled to the possession thereof; or, seventh, every lewd or dissolute person who lives in and about houses of ill-fame; or, eighth, every person who acts as a runner or capper for attorneys in and about police courts or city prisons, in incorporated cities or cities and counties; or, ninth, every common prostitute and common drunkard is a vagrant and is punishable by imprisonment in the county jail for not exceeding six months.

OIL HARDENED STEEL PLATES.—Messrs. Brown and Messrs. Cammell, the two great Sheffield firms, have recently been making some experiments on the effects of oil-hardening and annealing. A nine inch plate of steel was cut into two plates, each four feet square. One piece was left untreated and the other oil-hardened and annealed. They were fired at by the six inch gun with Firth steel projectiles weighing 100 pounds. The striking energy of the blow upon the untreated plate was 2389 foot tons, and the energy of the blow upon that which had been treated was 2378.5 foot tons. It is reported that in the latter case the projectile made an indentation of 10½ inches, so that light was just visible through the center of the hole at the back of the plate. The projectile rebounded broken into three pieces. The plate was cracked through, but was whole, and no material was splintered out either at its front or back. In the case of the untreated plate, the shot passed through, and the splintering of the steel around the hole in front of the plate spread over a space of 15 inches across. The splintering around the hole at the back of the plate covered a space of 31 inches across. The plate did not remain whole, but went into six pieces.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

BELL WETHER.—We made a visit to this claim this week. A substantial building has been erected over the shaft, with a small blacksmith shop attached. The sinking operations make slow progress, as the shaft is being put down in the solid ledge, with considerable water to contend against. On an average not more than a foot a day is made. The ore in its general appearance resembles the Zeile rock. It is undoubtedly a continuation of the same ledge. It is of the greenstone formation, and carries a heavy percentage of live sulphurets. The shaft is now down between 50 and 60 feet, the ore body showing solid and compact throughout. How wide the ledge is, is not known, as it fills the entire shaft. It is thought to be between 20 and 30 feet wide. There are two ore piles on the dumps, one from the tunnel and early sinking, the other from the shaft since the whim hoist was put up. It is all milling rock, in fact everything coming out of the shaft is milling ore. The surface dump is estimated to yield from \$7 to \$10 per ton, as indicated by prospects in band mortar. Mr. Bright, the owner, intends to have a test crushing made of 300 or 400 tons as soon as possible. Mining experts who have seen the property are unanimous in the opinion that it promises to develop into a big mine. The claim embraces 2000 feet along the lode. Prospect shafts and tunnels have been made at different points along the lode, embracing nearly one-half the claim, and in every case a large ore-body has been encountered, which has yielded a paying prospect. The claim is not half a mile from the court house, and the opening up of a large mine at this point will give a genuine boom to Jackson.

BELMONT.—The superintendent reports the ten-stamp mill running full time, the surface tunnel having reached a point where the ore-body is 20 feet wide.

MISCELLANEOUS.—There is no change in the situation of the Amador gold mine. The sheriff is still in charge, with no immediate prospect of a settlement. The suit of Trotter and others against the English owners is set for trial in S. F. about the middle of next month. The ten-stamp mill of the McKenzie mine at Irishtown, which has been idle most of the winter, is to be started up shortly, on ore from the McKenzie claim.

WILDMAN.—Cor. Amador Ledger, March 28: Everything connected with the mining industry looks promising. At the Wildman, under the able management of the superintendent, John Tregloan, the many additions and improvements about the mine and mill have been made without the necessity of levying an assessment. The 30 stamps are kept going steadily and everything is in fine condition. The new pipe that has recently been laid to run the mill independent of hoisting works is a great advantage. S. Higgins is foreman underground, and from this time on they expect the mine to pay regular dividends.

NORTH STAR.—The stockholders in the North Star Co. are once more elated over a change for the better in the prospects of their property. The latter part of last week a small vein of ore was discovered, which carries free gold and prospects well. They had drifted alongside it for some distance, and in picking into the side wall of the drift they accidentally stumbled upon the pay streak. A blast has been put in 18 inches into the wall, revealing some fine-looking quartz. Beyond this nothing is known as to its dimensions. Not much stir is made about the discovery, as the hopes of the shareholders have been raised so often only to meet the bitterness of disappointment. In the present case, however, there is some going, which is regarded as an excellent sign of developing into a permanent ore body. Altogether, the outlook is considered more favorable than at any time since the development was started. The Lincoln mine is running along in the usual way. The making of the pipe for the Mahoney is almost finished, and it is being rapidly put in position. Inside of two weeks the connection will be made with the canal, and it is expected that the stamps will at once be started.

SOUTH SPRING HILL.—The South Spring Hill Co. are hauling rock from the Median mine to their mill for the purpose of crushing and testing the rock, and, if it pays, will develop that property, as they are now the owners of that mine. We understand there are about 500 tons on the dump.

Butte.

SENT FOR MORE HELP.—Nevada Transcript, March 28: Work seems to be going ahead at the Gold Bank mine, Forbestown. Quartz is being taken out at such a rate that the reduced force in the mill cannot handle it and Thomas Goynne of this city has been sent for to resume his position there.

Calaveras.

MINE SOLD.—Calaveras Chronicle, March 28: The Linderax location, situated near Sandy Bar, and owned by J. A. Lefoy, was sold last week to Messrs. Lee Vandel and T. J. Tynan. Developments on this lead show a well-defined six-foot ledge of free milling and sulphureted ore which will yield on an average of from \$15 to \$20 a ton. Although the mine has been but little developed, still the indications are said to be very favorable for a good mine.

SPECIMEN.—Mountain Echo, March 28: We were shown a piece of quartz the other day weighing perhaps three pounds that must have contained at least \$200. It was picked up somewhere in the vicinity of Six-Mile creek. The lucky finder refused to tell just where.

Napa.

ANOTHER FIND.—Napa Register, March 27: Mr. R. F. Grigsby, the owner of the Palisade mine in Kings Canyon, was in town yesterday. From him we learn that Dr. Smith, a man who has done a great deal of prospecting in and about Mt. St. Helena, the other day "struck it rich" just above the Palisade, uncovering a ledge of quartz six and a half feet wide and going down no one knows how far. Mr. Grigsby ran some of the ore through his furnace and got a yield of \$90 to the ton in silver. The deposit is the continuation of a ledge cut in the development of the Grigsby mine and is known to

bear gold as well as silver. "If in what are recognized as mining districts," said Mr. Grigsby, "prospectors had the success they have lately met with in old Mt. St. Helena, such districts would now be swarming with gold-hunters, but no excitement follows the finds in our own county, notwithstanding their richness and the possibility of their extent." And Mr. Grigsby knows a mine when he sees it, for a good share of his life has been spent in bringing the hidden treasures of New Mexico, Arizona and California to the surface.

Nevada.

STEEP HOLLOW GRAVEL CLAIM.—Transcript, March 28: Messrs. Beightol, Greeley, Mackin and Vance, who have for a year past been drifting for gravel at Steep Hollow, expect to soon begin to realize good returns from their labors. The tunnel is in 600 feet. When it was in 500 feet they made an upraise and found that they were under the channel near the rim.

STRIKE AT THE NEW EUREKA.—In the New Eureka mine at Grass Valley, owned by A. Walrath and others, a six-foot formation containing stringers showing free gold has been struck.

NEW EUREKA.—Grass Valley Union, March 28: The fissure in the New Eureka mine at the depth of 600 feet is showing large stringers that contain plenty of free gold, and the find is likely to prove important. The work of development on the mine has been going on for several years, and this is the most encouraging discovery yet found. The fissure is now fully six feet in width, and the indications are that the stringers will soon make into a strong vein.

WYOMING CON. MINE.—The Wyoming Con. M. Co. has recently added to the length of its location by purchasing 1500 feet of adjoining ground, which makes a total length of 2500 feet now owned by the company. The location now extends south to the boundary line of the Boston mine, and north to the Lawrey. The ledge through the ground thus acquired is the same as that running through the ground of the Wyoming Consolidated, and it is the intention to start up work soon on the property.

PEABODY MINE.—Grass Valley Union, March 27: The Peabody M. Co. is about to apply for a patent for its ground. There are several residence lots on the surface of the location, which are held by virtue of settlement and occupancy. As the Peabody Co. does not wish to disturb these settlers, seeking only to secure the quartz vein beneath the surface, it is likely that an amicable understanding will be arrived at by which no contest will be made against the company obtaining a patent to its location.

A MINING PURCHASE.—Cor. Nevada Transcript, March 26: Wednesday Mr. Alf Tregidgo, the popular mining superintendent, purchased the Denning ground, or what is known as the Parr ledge. The property is located between the Empire and W. Y. O. D. mines, in Grass Valley district. Mr. Tregidgo will leave for San Francisco when the company will be organized and will probably be known as the Parr M. Co. Work will be commenced on the mine in a few weeks.

Sierra.

STRUCK GRAVEL.—Mt. Messenger, March 28: The good news that gravel had been struck in the B. M. Extension new tunnel was telegraphed to the president of the company here last Monday evening, causing the stockholders, who mostly live in Downieville, to feel much encouraged after their long waiting. This company located its claims, northeast of Forest City, in 1874; commenced its old tunnel in fall of 1878, and in 1882 found its first pay gravel. It continued working with varying success, owing to the peculiar shape of the ground, until the fall of 1888, when the gravel channel was found to have been cut off by a cross channel, and all work of taking out pay gravel ceased. A year before this time a new tunnel had been started in a branch of Kanaka creek, and over 1000 feet completed. Upon the giving out of the old channel, work was pushed on the new tunnel, which, it was expected, would tap the old channel at a point on the ridge near where the old Dan Cole road intersects the Henness Pass road. The tunnel has been pushed from that time until now, when the company's perseverance has been rewarded by finding the long-looked-for channel. For some time past the tunnel has been in a yellowish slate formation, and last week it was decided to raise a shaft. At a height of 54 feet above the tunnel, rim gravel, which prospecting as such gravel usually prospects, was found. The shaft was raised four or five feet into the gravel which showed, beyond doubt, that it was on the edge of a channel. The tunnel had been run in the meantime until it is now about 60 feet ahead of the shaft in soft white slate bedrock. When the tunnel is 100 feet beyond the prospect shaft another upraise will be made. The main tunnel is a little more than a mile long. The people of Forest City are very much pleased at the prospect of again having the old Bald Mountain tunnel worked in their neighborhood, as it means an increased measure of prosperity to them.

WIDE AWAKE.—More fine-looking gravel has been found in the Wide Awake and the boys are more hopeful than ever that they have good diggings.

Siskiyou.

BLUE GRAVEL.—Yreka Journal, March 26: The blue gravel mine of Lee, Lash & Co. at Greenhorn still continues to pay at the rate of \$150 a day, with considerable of the cemented gravel laid one side along with the boulders for washing or crushing, on account of the former not dissolving in the water, and the latter containing gravel that will not wash off until slaked by exposure to the influence of the sun and weather. The gravel run through sluices also pays good wages for washing a second time, and when the claim is opened more extensively a still larger force can be employed with better profit. At present only four drifters can work at a time with four men on surface attending to steam engine, hoisting apparatus and sluices, but another drifter to each shift will be added this week, and more will be added as the drifts are enlarged to admit extra hands. During last week each shift of four drifters only filled from 6 to 8 buckets every day in consequence of the blue gravel being so hard to dig, hence there could not have been more than two-thirds of the above amount washed on account of cemented quantities laid aside. Yellow gravel has also been found lately in the drifts, which pays equally as well as the blue gravel, and gravel containing red cement is also found occasionally. We visited the claim some days ago and found Lash, Perlin and Kenyon, the three working owners, washing some gravel while the steam pump was idle

that had been run through the sluices before, which occupied about four hours time and paid over \$7 to each man. It is believed this blue gravel formation extends down toward and across Yreka creek, with probability of rich deposits beneath the race track grounds and all the surrounding country beyond in the neighborhood of the Kildore hills. If prospects now being made at different points near Yreka develop the same blue gravel at bedrock we may anticipate lively times in mining operations, to bring a return of the flush days of Yreka during the '50 period, when Yreka Flats, Hawkinsville, Greenhorn, Deadwood, Humburg and other sections paid exceedingly rich. Louis Guilbert and Uley Brown are now sinking their shaft again at the Kildore hills, about three miles south of Yreka, going down about five feet a day. Upon reaching 80 feet they intend using a whim to hoist by horse-power, and say the prospects look very favorable for striking blue gravel at 100 feet or less below the surface, some blue boulders having already been found. The hydraulic miners at Oro Fino and Quartz valley have not yet been able to start up, but they expect to get ditches filled very soon, now that the warm weather and spring rains begin to melt the snow on the Salmon range. Senator Campbell's men are opening a new claim this season near Mugginsville in Quartz valley, and the Eastlice Bros. and Wright & Co. are anxiously waiting for water to start their giants at Oro Fino.

HENLEY.—Cor. Siskiyou Telegram, March 28: Our miners and farmers are all feeling jolly over the rainy weather. The miners will have a fair supply of water this spring, and farmers will have plenty of water for irrigating purposes. The most of our people here are more or less interested in mines, particularly blue gravel. Everybody is looking to see this one of the liveliest mining camps in the State in the near future. Undoubtedly, we have a genuine blue gravel channel here—one that will pay and last for years to come, always yielding a good revenue to the owners. At present it is hard to tell how extensive this blue gravel is. It has been traced for several miles, and prospects got all along the west side on rimrock. The east side of channel has not been found yet, and no one can tell how far east from west side the gold extends. The course of this channel seems to be from northwest to southeast. The rimrock on the western side dips to the northeast at an angle of about 30 degrees. The blue gravel or cement is generally capped over with sandstone. The Klamath river cuts this old channel deeper than any other place in the county, and those people who have locations along the river can work their claims with less expense than other places back from the river. The channel is located for several miles on each side of Klamath river. Some of the companies have spent considerable money to develop their claims, and as far as the work has gone, it has been satisfactory to the owners. There is no doubt but what there will be considerable machinery erected the coming season on different mines. The cement or gravel in most places is very hard and will have to run through stamp-mills or some other process to pulverize it to get the gold out of it. Jilson & Co. have the only mine on the blue lead that can be worked with hydraulicking. They have about 350 feet pressure, which cuts the cement in very good shape. They use considerable powder to break up the large block of cement that comes down. Their bank at present is about 75 feet high. This company has spent about \$30,000 to open their mine. They dump their tailings in the Klamath river. They are driving a large tunnel now for drifting purposes, so that the mine can be drifted and piped at the same time, most of the pay being near the bedrock. The company will work day and night. They have a good mine, and believe in working it and getting out the filthy lucre. Capt. Wilhoun & Co. have a good mine on south side of Klamath river, which prospects well as far as developed. Several other locations on the same side of the river will be prospected this coming summer. Now we have the Hill mine on north side of river, east of Jilson's mine. This claim has got lower draining facilities than any other location in the district. The company has a tunnel in over 100 feet, with good indications of getting pay. The Black Jack Co. have spent about \$8000 in developing their location. They have had some of their cement gravel crushed with very satisfactory results. At the present time, their mine looks very encouraging. A. Harvey and others have located on the north of Black Jack mine. They have done some developing work. A Portland company is having a shaft sunk on their location, work being done by contract. The El Dorado Co. has had a hole drilled 160 feet to bedrock and got good prospects. There are several other companies that are developing their claims. Everything goes to show that this in the near future will be a lively mining camp. Jones & Hazlett have some very rich prospects out of their quartz ledge on Hungry creek, three-foot ledge, good prospects make one feel happy.

NEVADA

Washoe District.

YELLOW JACKET.—Virginia Enterprise, March 28: Are shipping to the Vivian mill 40 tons of \$18 ore as per battery assays per day.

BEST & BELCHER.—1000 level: Repaired and cleaned out 50 feet of north drift. 1100 level: West crosscut No. 1 has been advanced 10 feet through quartz, giving low assays; total, 194 feet. At a point in east crosscut No. 1, 32 feet from winze, started northeast and advanced same 16 feet. Face in hard porphyry and stringers of quartz.

CON. IMPERIAL.—We are still following up and taking out small streaks of ore from the upper levels, and overhauling the old stopes.

SEG. BELCHER.—On the 600 level the east crosscut from the south lateral drift is out a total distance of 193 feet, having been advanced 26 feet since last report. The face is in clay and porphyry.

CROWN POINT.—The south drift on the 300 level, is out a total distance of 50 feet, having been advanced 29 feet during the week. The face is in clay and quartz, with small bunches of ore. The 500 level west crosscut was advanced 18 feet since last report, making a total length of 182 feet. The face is in clay and quartz. Have done no work in the lateral drift from the east crosscut on the 1100 level during the week.

BELCHER.—The south drift from No. 2 east crosscut, 200 level, is out a total distance of 79 feet, having been advanced 36 feet during the week. The face is in clay and porphyry, with streaks of quartz

giving low assays. No. 3 west crosscut, 300 level, has been advanced 32 feet since last report, and is now out a total distance of 208 feet. The face is porphyry with streaks of quartz through it. Have started an east crosscut from the 1500 south drift, which is out 10 feet.

CHALLENGE CON.—The joint Confidence and Challenge west crosscut from the north drift on the 300 level is out 35 feet, having been advanced 10 feet during the week. The face shows quartz having no value. The joint Confidence and Challenge raise from the 750-foot level is up 207 feet, 17 feet having been made during the week. The face shows quartz having no value. The joint Confidence and Challenge west crosscut from the north drift on the 1100 level is out 264 feet, 14 feet having been made during the week. The face is in clay. Work on this crosscut has been suspended for the present. The joint Confidence and Challenge east crosscut from the north drift on the same level is out 5 feet, having been commenced during the week; the face shows quartz having no value. The joint Yellow Jacket, Confidence and Challenge north drift on the 100 level is in 590 feet. The face shows quartz having no value.

KENTUCK CONSOLIDATED.—In the east ledge, 20 feet above the 1000 level, have started a south lateral from the winze, which has been advanced 8 feet in low-grade quartz. Started a raise from the east crosscut from the north lateral drift which is up 5 feet. Was able to save a small amount of pay ore. Have advanced the north drift from the west raise 17 feet. The face is in quartz.

JUSTICE.—The north drift on the 822 level was advanced 25 feet during the week, making its total length 468 feet. The face is in a mixture of quartz and porphyry, with stringers of ore running through it.

SAVAGE.—We have hoisted 552 cars of ore from the 500, 750, 800 and 900 levels and from the intermediate level the 1300 level. Shipped to the Mexican mill 545½ tons and milled 540 tons; average battery \$17.10. We have bullion on hand and at the mill amounting to \$17,729.40. The north upraise, 300 level, is advanced 137 feet; the top is still in low-grade ore. On the 800 level the north drift was advanced 30 feet, making the total length 85 feet from our south boundary. From this drift and from the stopes on the 900 level, 80 feet north of the Hale & Norcross line, we are stopping good ore. On the 950 level the south drift from the station was advanced 25 feet; total length, 156 feet; face in porphyry. On the 1400 level we have completed the station at the bottom of the winze. During the coming week we will start a north prospecting drift on the 1100 level from the north line of the Hale & Norcross ground.

HALE AND NORCROSS.—On the 100 level of Norcross the north prospecting drift is advanced 25 feet, the face in low-grade ore. On the 1400 level No. 2 west crosscut from south drift was advanced 15 feet; total length, 120 feet. This crosscut has reached the footwall of the ledge. The face of No. 4 west crosscut is in low-grade quartz. West crosscut No. 5 on our south boundary, started jointly with the Chollar Company, shows 40 feet of quartz, giving some fair assays. A new west crosscut has been started north of south boundary line and advanced some 30 feet, the face in quartz and porphyry. The main south drift of this level having reached the south boundary, is being advanced into Chollar ground at the expense of the company.

OCCIDENTAL.—Extracting ore of fair quality from the stopes on the 400 level. The south drift from No. 3 upraise, 40 feet below the 450 level, is in 58 feet and is showing fair-grade ore. South drift from north line, 650 level, is in 137 feet; face in low-grade quartz. North drift from No. 2 winze, 660 level, is in 237 feet, face showing low-grade ore. Have started a south drift from No. 1 winze, on 600 level, which is in fair-grade ore.

CHOLLAR.—We are making repairs on the 100, 500 and 650 levels. The west crosscut on the north line, 1400 level, advanced five feet; total, 45 feet; formation, quartz and clay. The south drift, 1400 level, is in 10 feet south of north line. Sent to mill 535 tons of ore, which averaged \$18.70 a ton, as per battery samples.

POTOSI.—East crosscut 400 feet south of shaft, 930 level, is out 235 feet; face in porphyry. The winze is down 144 feet below the 1300 level; face in porphyry mixed with quartz. East crosscut from the winze, 1300 level, is out 152 feet; face in porphyry and streaks of quartz.

ALPHA.—The winze 80 feet north of shaft, 500 level, is down 61 feet; the bottom is in low-grade quartz. The north drift from the east crosscut, 180 feet east of shaft, 600 level, is out 68 feet; face in low-grade quartz.

ENCHEQUER.—East crosscut on the north line, 600 level, is out 147 feet; face in porphyry.

CON. NEW YORK.—The north drift, 1100 level, is out 338 feet; formation, quartz. The west crosscut, 310 feet north of shaft, 1100 level, is out 35 feet; formation, porphyry.

SILVER HILL.—Northwest drift, 50 level, is out 85 feet; face in hard porphyry. North crosscut, 640 feet from winze, 160 level, is out 25 feet; face in hard porphyry.

WARD COMBINATION.—East drift from 1800 station is out 905 feet; face in porphyry and clay.

ANDES.—The east drift from the main north drift on the 420 level, which connected with the winze from the 350 level, has been timbered up and the connection completed. We are now easing timbers in the main north drift. East crosscut from the south lateral drift on the 420 level has been advanced 18 feet; face in a formation of vein porphyry and clay.

UTAH.—725 level: In the main west drift, at a point 140 feet from the shaft, a south drift has been advanced 56 feet. This drift is running in a quartz streak averaging two feet in width, showing some value by assay.

Danville District.

SILVER.—Belmont Courier, March 28: O. S. Wailles of Fish Lake valley has resumed work on his mining claims at Danville district. He is extracting some rich silver ore. The prospects for Danville district are excellent.

Arabia District.

EXAMINING THE MINES.—Silver State, March 28: An Eastern mining expert passed west on Tuesday for the purpose of examining the Arabia mines, seven miles from Trinity mining district and about four miles from old Oreana. The Arabia mines

should pay handsomely by the cheap process now in use, as the ore is easily broken and there is abundance of it in this district. The Montezuma, Jersey, Dunderberg and Old Daisy, Series and other lodes have plenty of good ore in them and but little capital is required to make a big boom.

Morey District.

OUTLOOK.—Belmont *Courier*, March 28: The outlook for Morey is good. The mines are looking well and it is confidently expected that considerable work will be done on the mining properties in that district during this spring and summer.

Tuscarora District.

NAVAJO.—*Times-Review*, March 28: The 350 stopes are looking well and the grade of ore is getting higher.

NEVADA QUEEN.—North drift on 650-foot level has been extended 12 feet, and crosscut started east, which has been run 13 feet in hard porphyry.

NORTH BELLE ISLE.—North drift from Belle Isle 450-foot level extended 18 feet. The ore shows spots of ruby ore. Average assays of the ore \$102, and is improving. The 500 stopes yielded 16 cars of first-class and 119 cars of concentrating ore. North intermediate drift from No. 4 chute, 600-foot level, extended 18 feet. The face is all in vein with seams of ore coming in.

COMMONWEALTH.—Fourth level—West crosscut has been extended 27 feet; no material change. East crosscut extended 30 feet, cutting another flow of water and seams of clay. North drift in the vein extended 22 feet in low-grade ore. A drift south has been started in the vein, and in 11 feet. Putting in turntable and track has delayed the progress. Started work in both drifts last night and good headway will be made.

NORTH COMMONWEALTH.—First level—Has produced 20 carloads of first-class ore; average assay \$258 per ton, and 37 carloads second-class ore; average car sample, \$32 per ton. Second level—North drift from west crosscut advanced 27 feet, exposing 12 inches fair-grade ore, assaying from \$30 to \$277 per ton. Fourth level—East crosscut has been extended and timbered 33 feet, cutting clay seams; rock is the same as cut under the vein in east crosscut of Commonwealth.

Robinson District.

OPTION FOR A BOND.—White Pine *News*, March 28: Mr. J. A. Keating and Joseph Gans accompanied by R. H. Frank of Cherry Creek, spent five or six days here the latter part of last week and the first of this, examining the Joanna group of mines in Robinson District. The two first named gentlemen are experienced mining men of Montana, who can command any amount of capital if the venture warrants its expenditure. These gentlemen made a thorough examination of the Joanna and adjacent mines and expressed themselves as well satisfied with what they saw and the general formation of the mineral belt. They also went through the Chainman mine, which they had no hesitation in pronouncing a very valuable piece of mining property. They took their time, took no one's say so, but "panned out" for themselves, and the result has been satisfactory. We learn that Messrs. Keating and Gans got an option of 60 days for a bond on the Joanna, Joanna No. 2, Cloud and Great Western. The terms of the bond, which are perfectly understood between the parties, we are not at liberty to make public; but, we are informed, it is on such a scale that as soon as the bond is signed, the construction of a 20-stamp mill will be commenced at once and they expect to have it completed by the middle of July.

Columbus District.

A BRIGHT OUTLOOK.—Walker Lake *Bulletin*, March 28: Candelaria still continues to be a thrifty mining camp. The monthly pay roll amounts to \$50,000. There is sufficient ore in sight in the Mt. Diablo to supply the milling capacity for a long time. There is a large force of men constantly employed at the Holmes. A new pipe line will be laid, the present line being inadequate to supply the demand. The water is scarce a distance of 28 miles. Captain Channel, superintendent of the Princess, states that his company is prospecting and opening up new ground but not taking out any ore at present.

Oseola District.

HYDRAULIC MINING.—Cor. Nevada *Transcript*, March 22: As I look out I can see snow in every direction, although it is all gone around the mine. Up on the hills there is enough in sight to insure us a pretty good run of water for this season, as we have both ditches in order to catch the first water that comes in the spring. Unfortunately for us, last spring the new ditch and flumes were not completed until the best of the water supply was gone on that side of the mountain, and the ditch being new and cut through very loose ground in some places, causing it to leak more or less, gave us but little benefit; but now it is pretty well soaked up and I think capable of carrying its full capacity. We have flumes and pipe laid and monitors in position to work in good shape as soon as water comes. The weather has moderated considerably during the past week. The ice is melting fast, and there is quite a nice little stream of water in the old ditch which will melt the ice out pretty quick. There has been quite a stir here among prospectors this winter, mostly done through the dry wash process. Quite a number of locations have been made, and all the machines in the camp are being operated with very encouraging results. I have two locations myself, one of which is a bonanza as far as developed. I located it in January, but on account of storms, and cold windy weather could not do much toward opening it up. The formation is mostly lime and gravel all mixed up and very hard, resembling Portland cement, making it slow to work, as it has to be all broken up fine for the machines. The prospects range from \$4 to \$15 per hundred shovels. The regular way of working the machines is to count the number of shovels as you throw them into the machine, and clean up every one hundred shovels separately. There are several other locations adjoining mine that pay nearly as well. I think I happened to strike on the best part of my ground, as it is on a sort of a bar where the gravel is shallow.

Dun Glen District.

PROSPECTING.—Cor. Silver *State*, March 28: The mining industry, which, after all the bluster about water storage, still remains our only well-grounded hope for the return of anything like the good old times, seems almost paralyzed by a complication of adverse circumstances; yet a few hard-

palmed prospectors are still prospecting an intelligent and patient search for the hidden treasures of the mountains. Of our small population, nine men have worked steadily all winter developing claims and taking out ore for milling or shipment. Hendra Bros., owners of the Golden Chariot mine, have, during the winter, completed a tunnel started several years ago and tapped the ledge about 80 feet below the level of the workings. This will greatly facilitate the extraction of ore and enhance the value of the mine. The ledge is over four feet, and although not of high grade, is expected to pay well. They expect to start their mill in a week or two, and are hopeful of an all summer's run, as water will be abundant and the supply of ore is far in excess of the milling capacity. S. C. Thomas and his brother James have been busy all winter on his mine, taking out ore which fairly shines with yellow metal. It only takes a few tons of this ledge to yield a thousand dollars, it being small and of high grade. Nelson Bros. are hunting for a body of rich ore which they are hopeful of yet bringing to light. Armata & Miglu are shipping some fine ore taken out of the Monroe mines during the winter. Rich'd Eva has been prospecting for placers in Monroe canyon with success, though the work was prosecuted under great disadvantages.

Wild Rose District.

THE PARADISE PROPERTY SOLD.—Silver *State*, March 27: The final transfer of the Paradise Valley mining and mill property was effected yesterday at San Francisco and final papers executed. The property consists of the Paradise and Wild Goose mines and their several extensions and the mill property of the Paradise M. & M. Co. Said property was sold and deed made out to Doctor Hanson for a Boston syndicate, several members of which arrived in Nevada in company with Dr. Hanson about three weeks ago. They immediately visited and examined the mines and other property belonging to the company and were well satisfied. They then returned to Winnemucca and in company with Attorney MacMillan they examined the records. After being satisfied with the title, they repaired to San Francisco, and after a thorough examination of the company's books, the deal was closed yesterday. This company expects to expend about \$200,000 before receiving any returns. They will place an electric plant at the mouth of No. 6 tunnel, at the lower end of the canyon, and receive the power from Hardscrabble ranch on Martin creek, about four miles from the tunnel. The plant when finished will cost all of \$150,000. It is expected to have a capacity of 150 tons per day. As there are thousands of tons of ore in tunnels No. 4 and 6 that will go from \$14 to \$20, it will be a very easy matter to supply the plant with that amount of ore, as the ore will be dumped from tunnel No. 6 directly into the mill. We may expect in a very short time to hear of lively times in Paradise, and too much praise cannot be given Dr. Hanson for the successful manner in which he accomplished this transfer of the Paradise property. It will not only create a boom in Paradise, but it will have a tendency to bring other capitalists into this section of the country to look at other properties. The outlook is certainly much brighter for the future.

ARIZONA.

GLOBE.—Cor. Arizona *Enterprise*, March 26: The mining news is good, the prospecting of the Bisbee Co. we learn is satisfactory; the same indications of large bodies of rich copper ore is showing up on these claims as in the Old Dominion. There is no doubt but the claims are all that the company want. No one can tell what they will do, or when active operations will commence. All the chlorides are getting good silver ore; the Rescue is yielding large bodies of rich ore and no doubt will be a big mine. Good news comes from Pioneer; John Newman with his concentrator is doing a fine paying business with any quantity of ore for the purpose in sight.

CATOCIN.—Prescott *Courier*, March 31: Superintendent Johns says that the mine is looking well. He has two teams steadily engaged in hauling ore to the Prescott ore works.

SENATOR.—Supt. J. J. Williams has secured a large Pelton wheel and will run the Senator mill with it whenever there shall be sufficient water in Hassayampa creek. John S. Jones' plant, in Big Bug district, consists of a 5-stamp battery, slimer, concentrator and tables, which he will run by power of a 24-inch Pelton wheel. He has built a mile of fluming; will put in piping. He will have a fall of 180 feet. His intention is to have ore taken from his several ledges by contract.

NEW FIND.—Prescott *Courier*, March 29: Frank Kienle showed the reporter some handsome free gold quartz yesterday which assayed \$54 gold and \$3.20 silver from a new find—the Cumberland and extension—which he located two years ago. He has two feet of honeycomb rock in the ledge which assays \$300 gold. These properties are a quarter of a mile from the Railroad mine and two miles from the Blue Dick.

COLORADO.

FIVE THOUSAND DOLLARS PAID.—Aspen *Times*, March 28: The Argentum-Juniata Co. has paid in to the city Treasury the first installment of \$5000 for the privilege of mining under the streets and alleys of a portion of the east part of Aspen. The company was not obliged to pay it until the 30th of March. The next payment is to be made in 18 months.

THE BUSHWHACKER.—The Bushwhacker Co. continues development work without stopping to increase the output, which amounts to 10 or 15 tons of good ore per day. During the present month the work has been done principally in the fourth level north, which is also in good pay ore, and an upraise has been run from the fourth to the third level, with ore all the distance. Just how wide this ore chute is has not been determined. If it continues down to the Cowenhoven tunnel, a distance of about 1000 feet on the dip, the wealth of this body of ore alone will run up into the millions. The indebtedness will soon be liquidated and a receiver's receipt issued, when the stockholders may begin to expect some remuneration for their investments in the way of dividends.

THE LITTLE ANNIE.—Superintendent Atkinson yesterday telephoned the manager that he was in good ore in several places on the Annie. S. L. Hansbrough and Charlie Kutzleb came to the city

with some of the ore late in the evening that looks as if it would assay way up in the thousands.

THE WILMINGTON.—J. W. Nugent, who, with the Continental Divide Mining Investment Co., is working the Wilmington of the Climax group, was in the city yesterday feeling jubilant over some fine-looking ore he had struck in the north drift. He thinks that a big ore body is being tapped and says he will quit the country if he does not have pay ore in 30 feet.

THE PARK-REGENT.—Manager Wright is expected home to-day from New York, where he sold enough Bushwhacker stock to finish paying for the Park-Regent and Tiger. His property is looking well. Development work in the north end of the Park has been commenced through the Iowa shaft. Mr. Wright thinks he has the down-hill pull on a large portion of the world in that part of his ground.

DAKOTA.

BLANQUILLA.—Deadwood *Pioneer*, March 27: Development work on the Blanquilla group of mines continues steadily. There is now five feet of ore in sight, overlaid by a three-foot vein of manganese ore, that carries a little gold and silver. An assay of five samples from the ore body gives an average value to the ore of \$38.29. This property is located on Squaw creek, and is one of the most promising properties in the Hills.

KEYSTONE CHLORINATION WORKS.—Messrs. Keith and Cameron returned yesterday from Chicago, where they had been purchasing the new machinery for the Keystone Chlorination works. The first carload of material will leave Chicago about April 10th, and the remainder will be shipped on the 23rd. The rock-breaker and pulverizer is a new improvement of the Gates style, combining a crusher and pulverizer that grind up the ore to allow it to pass through a 10-mesh screen. This is the first crusher of the kind sent out of the Chicago works, and Mr. Gates will be present himself to witness its workings. All the ore that is too coarse to pass through the screen is hoisted up by an elevator and sent through the crusher again. The roaster weighs 42,000 pounds, and will be capable of treating 50 tons of ore per day that does not carry over 10 per cent sulphur. There will be three pumps, one for water, one for acid and the third for chlorine solution. A compressor is ordered, for compressing the cakes of sulphides. The barrels have been ordered from Fremont, Neb., as the house there underbid the Chicago concerns. One barrel, capable of treating 24 tons of ore daily, was to be completed in ten days, and the other about May 1st. The engines and other machinery were ordered at Chicago.

IDAHO.

DELAMAR.—Cor. Idaho *Statesman*, March 28: Since my last the blower at the mine has been put in place and the large pipe made by Theo. Phillips of Silver City has been placed in the tunnel and connections made with pipes leading to all the different sections of the mine where needed. The blower was started up on the 12th, everything worked to a charm and the boys are now fully supplied with plenty of good air throughout the different workings. In many places it was badly needed as the air was exceedingly close, the chambers warm and the powder, smoke and gas would never entirely disappear. It has been found that the wires conveying the power from the dynamo to the electric hoist at the winze are not large enough to run the hoist and new and larger wires were accordingly sent for and are on the way.

THE NAY AUG SHUT DOWN.—Wood River *Times*, March 28: The Nay Aug mine was shut down temporarily yesterday, it being impossible to work to advantage with the present machinery. It will probably remain closed for a month or six weeks, or until the roads become passable, when operations may be resumed. One of the first moves in that direction will probably be the erection of a concentrating mill; as there are between 800 and 1200 tons of second class ore on the dump, besides large quantities in place in the mine.

FROM CLAYTON.—The Custer mill, which has been shut down for over a year, will resume operations about the 1st of May.

LOWER CALIFORNIA.

ALAMO.—Lower Californian, March 26: The E. Paso mill is running on rich ore from El Paso mine G. F. Dow and partner are at Tableta. The saw mill will start up at once. The Frenchmen's mine over Tomasa's eyebrow pays \$100 a ton in red gold if it pays a cent. The Manzanita mill is running and Col. Lane's mill is crowding ahead. All the other mills, also, are in full blast. Parties from the Cucapa placers arrived at the saw mill last week and reported rich ground. They returned at once after getting supplies. It is reported that silver has been found in Valle Trinidad. The floaters and kickers are waiting for the boom in San Quintin to drift down that way. Speaking of San Quintin, a mining man here says that it is bound to be the center of mining activity soon. Valladares, Santo Domingo, Agua Dulce, Socorro, San Fernando, Calamajue, Calmali and other camps will be tributary to San Quintin. Nothing new has developed in the vicinity of Alamo or in the mines during the past week. The Aurora has started on its upper ledge, the Boracha, where promising ore is in sight. The ore in the regular ledge is all stopped out. The Indio is sinking under the steam drill, and drifting is continued on the Ulises. The lessees of the Montezuma are doing a little development work. The El Paso is drifting.

MONTANA.

BIMETALLIC.—Phillipsburg *Mail*, March 26: The bimetallic company are now going ahead with the work of excavating for the new 50-stamp addition to their mill at Clark with all possible speed. All the men and teams that can be worked to advantage are busy on the ground, and material is constantly arriving for the new structure, which it is thought will be completed and ready for use not later than July 1st. When this addition is finished the bimetallic company will have 100 stamps dropping under a single roof, which will be the largest dry-crushing mill in the world.

There can be but little doubt that when this new addition is completed it will not be long until the bimetallic will take first place among the silver pro-

ducing mines in the world. The work of building the new addition has already shown its effect in the camp, and increased activity in all branches of business is noticeable.

NEW MEXICO.

GOLD.—Southwest *Sentinel*, March 26: N. Bell brought down last week gold to the amount of 65 pounds, valued at \$124,80, and his concentrates, which will net as much more, all from about 400 tons of ore taken from his mine. Mr. Bell says all he wants is a few weeks' notice when the two-pound gold brick is wanted for the world's fair, and he will get it ready. He will take it out of the ore in his mine very quickly. Frank C. Bell has uncovered a body of ore in one of his claims at Pinos Altos that runs 53 per cent lead, 18 ounces silver and \$3 in gold. It is rumored that something will soon be done at Paschal and Santa Rita in the copper line. C. E. Miller has a fine showing in the Langston mine at Pinos Altos. He was down to Silver City last week endeavoring to secure facilities to have his ore treated. We notice the iron ore shipments are increasing from Silver City; 15 carloads during the week went out over the A., T. & S. F. R. R. H. H. Betts made a shipment of high-grade silver ore to the Rio Grande Smelting Co. last week.

CARLISLE.—James Tong, of the Carlisle Co. reports the new camp about two and one-half miles west of Carlisle in a flourishing condition. From the Alabama Mr. Tong has shipped three cars of ore, the first averaging \$76 per ton, the second car \$220 per ton and the last car \$750 per ton. The ore taken out while sinking the shaft paid \$125 per foot. Belton and Reardon, the owners of the Julia, have been working steadily and shipping \$75 ore. R. M. Rucker has a 12 foot lead which averages over \$30 per ton. Work is progressing on the Gold King, owned by Epley, Bailey and Tong. Twenty-three tons of ore worked in the Carlisle mill averaged on the plates \$16 per ton. Ore is still being shipped from the Jim Crow, the first class averaging from \$200 to \$250 and the second-class about \$60. This new camp has but recently come to the front as a producer, and with the exception of two or three of the claims all of the rest have been located within the past six months. The veins are all true fissures of a good average width and a grade that will pay to ship. The bodies of ore are simply wonderful, and in a short time the camp will be the most prosperous in the country.

OREGON.

THE EASTERN OREGON PLACERS.—Bedrock *Democrat*, March 26: Owing to the unusually heavy fall of snow in the mountains in Eastern Oregon, this season will be a splendid one for placer mining. There will be water in the canyons and gulches until late in the season. This will greatly facilitate the operations of the miners. Where canyons or ravines have crossed mineral veins containing gold, in their course down mountain sides, more or less of the shining metal will be found in the gravel. As there will this season be water with which to prospect in many places where in ordinary seasons no water is found within miles, it is likely that rich placer ground will be struck on not a few benches and flats, where heretofore the advent of the pick and shovel were unknown. From Luther D. French, who was in this city yesterday, the *Democrat* learns that the snow is still about 14 inches deep in Sumpter valley and in the mountains it is much deeper than it was last season. The gentleman states that it is packed solid and will disappear very slowly. It is probable that quite a number of placers in the Auburn district which have remained idle for several seasons past, will be worked this. The outlook for the placer miner this season is undoubtedly most flattering.

UTAH.

ORE ON THE MARKET.—Salt Lake *Tribune*, March 25: To-day there will be 700 tons of Horn Silver ore on the market, and ore-buyers will have a lively time bidding for it. Shipments from this mine have become quite regular and also quite large.

MOVEMENT OF ORES.—The movement of ore in the camps near this city has almost stopped. At Bingham the roads are in a wretched condition, and this has stopped most of the ore hauling. At Park City there is snow, slush and mud, and it was snowing more the past two days. The roads to the mines are too bad to get ore down. It is probable the Crescent will not be able to send any more ore down until the snow is far enough gone to permit operating their tramway. Their new larger locomotive should be received by that time and enable more rapid ore transportation to the concentrator. At Tintic there is but little snow in the towns of Eureka and Silver City, but lots of it on the hills, while between the mud and snow, ore-hauling is about at a standstill.

THE BUCKHORN.—The Buckhorn, at Ophir, under the new management has a force of 25 men working on the lower levels, and is opening up large bodies of ore. Since snow is two to three feet deep up about the mine, no ore is being shipped at present, but it will move fast in the spring.

SMELTER.—Salt Lake *Tribune*, March 26: P. A. H. Franklin returned yesterday from his visit of five weeks to New York, Boston, Philadelphia, etc., whither he went in the interest of his mining operations. One object was that of arranging for a big smelting and refining plant near this city, and in this mission he has fair promise of success. This matter, however, is not in condition to make fully known to the public what has been or what is likely to be done in the near future. In the meantime the operations of his big group at Bingham, the Niagara will go ahead and his plans of making that a great property will be carried forward as fast as possible. Mr. Franklin found much interest in mining among the capitalists with whom he came in contact.

ORE AND BULLION SHIPMENTS.—Park *Record*, March 28: The Ontario mill shipped 24 bars of bullion this week, amounting to 16,386.15 fine ounces silver. Jerry M. Richardson shipped to-day 128,000 pounds of first class ore. He has a large tonnage on the bill that he cannot get down just now owing to the bad condition of the roads. During the week there was received at and forwarded from the Mackintosh sampler the following lots of ore: Ontario, 256,970 lbs.; Crescent, 283,400; Anchor concentrates, 205,480; Cumberland (first shipment), 1750 pounds; total, 787,600 pounds.

MECHANICAL PROGRESS

Mechanical Progress in China.

The Chinese, in many respects are a rational and practical people. There are many among their learned and influential men, who have become quite thoroughly imbued with the value of the progressive ideas which have interested "the outside barbarians" during the last century. But unfortunately the stationary and superstitious notions which have been inbred into the common people during the thousands of years of their isolation as a nation, are very difficult of any sudden eradication. Such would have been the case with the masses of any people, who have so long been accustomed to thoughts and ways handed down from so many generations under a continuous and uniform mode of government and education.

But if their present intercourse with foreign nations is kept up for a series of years, their antiquated notions will soon give way and China will step out of her Rlip van Winkle sleep and come to the front with a power and influence that will astonish the world.

That the Chinese are really a practical people, and that the work of revolution has already commenced may be inferred from what follows:

During a recent anti-foreign-devil riot at some place between Tongfu and Kaiping the mob, by way of emphasizing its patriotic sentiments, destroyed a good length of railway that has recently been carried through the district. The local mandarin—a Chinese Raskinle apparently—instead of using the forces under him to quell the riot sent his soldiers to assist in the pious work. The embankments were leveled for some distance, and the rails thrown into the river, and an attempt was made to destroy the bridges. Mr. Kinder, the engineer of the line, laid the state of the case before the Taotai of Tientsin, who is the head director of the undertaking. The Taotai sent for the mandarin, and addressed him thus: "To please yourself and your friends you have destroyed the railway track. To please me you will put it back just as it was before. If, one month from to-day the trains are not running the same as before, you lose your head and your family and ancestors are disgraced."

"Mr. Kinder estimates the damage and loss by non-running of trains at 50,000 taels (about \$12,500) which sum you will have to pay out of your own funds to the company. For labor, all your officials, soldiers and the townsfolk will work as you direct, receiving no money for their labor, and all salaries are stopped until the repairs are complete. I shall appoint a board of punishment to return with you, with power to torture and imprison anyone who makes the least disturbance or trouble." The mandarin begged for mercy on the plea that, as the country was all under water he could not possibly get mud and stones wherewith to build the embankments. The Taotai saw the force of this plea, and said he would give him a chance. He could pull down any of his forts he liked in order to provide material for the repair of the railway, and he would give him three months after the railway was completed to rebuild his forts at his (the mandarin's) own expense. In rather under three weeks the trains were running again, and they are now rebuilding the forts. How long would it have taken to bring about the same results in England?—*London Truth*.

Much trouble in the way of railroad building has been encountered in China on account of the multiplicity of graveyards and the prejudice which exists against disturbing places of sepulture. A road lately surveyed between Kowloon and Canton has been for some time held in abeyance on this account; but even that prejudice has now been overcome and the modern symbol of progress, the locomotive, will soon be seen in the great city of Canton. This same prejudice stopped progress on the Boston and Providence road in 1835—one of the very early roads in this country. People turned out with arms to drive away the railroad workmen; but better counsils soon prevailed, and work went on.

It is not at all likely that there will be any more railway demolition in that province. Another evidence of the really progressive steps which China is now making is found in the efforts now being made by the Government of that country toward the establishment of extensive and complete iron and steel works. About a year ago two English engineers went to China to take charge of the work for the government, and the preliminary arrangements have been made. The site chosen for the works is near the junction of the Han and Yangtze rivers, opposite the city of Hankow, in the province of Hoo Pe. The plant will include two large blast furnaces, capable of producing about 100 tons of pig iron daily. There will also be a complete Bessemer steel plant, with two five-ton converters and all the necessary outbuildings, casting cranes, blowing engines, etc. The product of this plant will be made chiefly into rails and there will be a large rail mill with all its appliances for this purpose.

It is officially stated that the manufacture of rails for future railroads is one of the chief objects of the Chinese government in building these works. There will also be a small Siemens-Martin open-hearth steel plant for the manufacture of ship-plates and mild steel for small fire-arms. There will be a very complete iron mill, including 20 puddling furnaces and a plate and bar mill. The works will cover about 40

acres, and will be traversed by numerous small railway tracks for the handling of materials and products within the works. The contract for the machinery for the entire plant was placed with an English house, and the specifications call for the delivery of all the material early in 1892. A large quantity of the machinery has already been shipped, and all of the blast furnace material is now on the site of the works.

There is good reason for believing that at no distant day China will take a stand high among the nations of the earth, as a progressive and powerful people. When she does so, San Francisco will occupy a position of the highest commercial importance in relation to the trade not only of China, but of all the Orient as well. The four great commercial cities which will then sell the markets of the world will be London, New York, San Francisco and Shanghai or some other favorable city location which may grow up on the coast of Eastern China, not now known to the world.

COMMON SENSE IN MECHANICS.—No amount of education and practical training will make a thoroughly good and competent workman of a man who has no inclination or natural ability for a certain line of business, and especially is this true of the mechanic. The construction of machinery at the present time is an art that calls for a man with natural ability and adaptation. It is not merely a following out of theoretical plans and calculations. Neither is it a work in which handicraft alone can succeed. It may be true that a large proportion of workmen are what might be termed skilled artisans, who are capable of doing the part assigned them in a creditable manner, and sufficiently well to make the completed mechanism a perfect-working and well-proportioned production. But there is something more than this in the trade. These are not the men who work out or suggest improvements, who can be trusted with the more important work of designing and constructing. There is no trade in which there is a larger field for the display of common sense than in the machinist's trade. It is the exercise of this very important element of a man's make-up that earns for him a reputation and a standing that no amount of theorizing will bring. There are so many different ways of accomplishing the same result that it requires a man of good judgment and a quick perception to see which way is best in a particular case, and very often calls for the exercise of good common sense.—*Ex.*

A FIVE-MILLION DOLLAR BATTLE SHIP has just been launched at Portsmouth, England. She is called the Royal Sovereign and is the largest war vessel ever constructed in England. She has a displacement of 14,150 tons, and an indicated horse-power of 9000 natural draught, and 13,000 forced draught. Her forced speed is to be 17½ knots. She is protected by a steel belt 280 feet in length, 8½ feet in height and 18 inches thick. Above that is a three-inch steel deck, and it is terminated by transverse armored bulkheads, the lower edges of which rest on steel decks extending down in curves to stem and stern. Above the belt the broadside is protected to a height of 9½ feet above water by five-inch steel armor, the battery being shut in fore and aft by steel bulkheads. On the barbette towers the armor is 17 inches thick, the protection being carried down to the belt. The principal armament consists of four 13½-inch 67-ton breech-loaders, disposed in two towers, all four guns being available on either broadside. The secondary armament consists of ten 100-pounder, 16 six-pounder and eight three-pounder quick-firers. The Royal Sovereign is one of a group of eight first-class armored battle-ships embodying the views of a majority of the most experienced naval architects regarding speed, coal-endurance, freeboard, armament, and armor protection. The design of the battle-ship is more like that of the Boston than any other warship in our navy. The estimated cost of the vessel is \$5,000,000.

IMPROVEMENTS IN PULLEYS.—An important improvement has been made in the covering of pulleys, by which it is claimed fifty per cent more power can be transmitted, and all slipping is reduced to an imperceptible factor. This system comprises the following points: It consists in the employment of a specially prepared leather covering for the pulley, which is extremely soft and elastic, and never glazes by the rubbing action of the belt, as is the case when ordinary leather is employed for this purpose. It is applied to the pulley, and held firmly to it, for all time, by means of a special cement, which is soft and never hardens like ordinary cement or glue. No rivets of any kind are employed, but the leather covering is firmly attached to the iron of the pulley by the cement alone. Covering iron pulleys with paper is sometimes practiced, the covering being done as follows: First cleanse the pulley from grease with sal soda (washing soda). Then scotch the whole surface with a file. Wet with dilute nitric acid for a few minutes to deaden the scratches, clean with water, and dry. Apply the paper by winding, using the strongest glue, or the paper may be wetted with tannic acid and then applied as above. Some prefer to add a tablespoonful of glycerine to a quart of glue and then apply hot. Turn off the edges and apply a coating of common shellac.

EDISON'S PROFITS from his electrical inventions are estimated at not less than \$12,000,000.

SCIENTIFIC PROGRESS.

Grass and Its Mission.

Next in importance to the divine profusion of water, light and air, those three physical facts which render existence possible, may be reckoned the universal beneficence of grass. Lying in the sunshine, among hut-troops and dandelions of May, scarcely higher in intelligence than minute tenants of that mimic wilderness, our earliest recollections are of grass; and when the fitful fever is ended and foolish wrangle of the market and the farm is closed, grass heals over the scar which our descent into the bosom of the earth made, and the carpet of the infant becomes the blanket of the dead.

Grass is the forgiveness of Nature—her constant benediction. Fields trampled with hattle, saturated with blood, torn with the ruts of cannon, grow green again with grass and carnage is forgotten. Streets abandoned by traffic become grass-grown, like rural lanes, and are obliterated. Forests decay, harvests perish, flowers vanish, but grass is immortal. Belegged by the sullen hosts of winter, it withdraws into the impregnable fortress of its subterranean vitality, and emerges upon the solicitation of spring. Sown by the winds, by wandering birds, propagated by the subtle horticulture of the elements which are its ministers and servants, it softens the rude outlines of the world. It evades the solitudes of deserts, climbs the inaccessible slopes and pinnacles of mountains, modifies the history, character and destiny of nations. Unobtrusive and patient, it has immortal vigor and aggression. Banished from the thoroughfare and field, it hides its time to return, and when vigilance is relaxed, or the dynasty has perished, it silently resumes the throne from which it has been expelled, but which it never abdicates. It hears no blazonry of bloom to charm the senses with fragrance or splendor, but its homely hue is more enchanting than the lily or the rose. It yields no fruit in earth or air, yet should its harvest fail for a single year, famine would depopulate the world.

THE RELATIONS OF MEN OF SCIENCE TO THE GENERAL PUBLIC was the title of the address of T. C. Mendenhall, as retiring president of the American Association for the Advancement of Science, at its annual meeting in Indianapolis for the year 1890. The main points of his theme were:

1. The particulars in which scientific men fail as exponents of science among their fellows. Under this head is named, with proper qualification, the fact that such men are sometimes unable, or unwilling, to present the results of their labors in form intelligible to intelligent people.

2. Men of science are liable to fall into the error of assuming superior wisdom as regards subjects outside the lines of their specialties.

3. Men of science are not always reasonably free from egotism in matters relating to their specialties, particularly in reference to authority and attainments in the same.

4. Another element of weakness in scientific men is that they are often less "practical" in their work than they should be. Sometimes they even despise the useful and practical in science, and their dignity is disturbed when an honest and innocent layman asks what the use of this or that discovery is. This we deem one of the most important points of the address, because the fault is so commonly noticed and spoken of by intelligent laymen. We have ourselves been recently ashamed of some of our prominent scientific men for grievous errors in this way.

5. The last point of the paper is the demand which the public may justly make upon the man of science, that his interest shall not be less in public affairs than that of other men. The paper, as a whole, is well calculated to call the attention of scientific men generally to a line of usefulness and an opportunity for good not fully appreciated heretofore.—*Sidereal Messenger*.

THE SCHISOPHONE.—This recently invented instrument for detecting flaws in iron, from which so much was expected, seems to have greatly disappointed those for whose benefit it was designed. In common with many of our contemporaries, we have made several favorable allusions to it; but the *Scientific American* now gives the following discouraging paragraph: Railroad men, especially, will regret that the schisophone, an electrical instrument invented by a Frenchman for detecting flaws in metal castings and forgings, is not realizing the promises made for it, for in the newer railroad science, though sturdy and ingenuity have found means of greatly lessening danger through broken axles and wheels, through collision and the like, no amount of inspection has sufficed to detect flaws in rails and to prevent rail-splitting. Hammering was the only known test, a fairly accurate one, it would seem, when the defect was of an exaggerated description, the human ear being sensitive enough to note a certain dullness in the sound which the hammer gave, but it long since became evident that flaws could exist and the blow of the hammer give no recognizable signal. The schisophone could unerringly do this, had, indeed, accomplished it repeatedly. That is what the first reports of the instrument declared, indicating the defective point, and he-

ing corroborated when the rail was broken and examined. This seems now to have been an exaggeration.

RAIN RECORDS in various parts of the State show not only great variations in different and distant localities, but also important variations in quite near localities and under the same topographical conditions. Even different portions of a large field, without any marked differences of elevation show quite a difference in rainfall. This is accounted for from the fact that the rain does not fall equally from all parts of a cloud. The condensation proceeds diversely in different parts. Rain gauges under different portions of the same cloud would record variously. The edge of the cloud might pass over one instrument, while the center would pass over another. Then again, rain falls from different heights, under which conditions there would naturally be varied amounts of condensation.

A FINE POINT.—Experiments made by Pratt & Whitney, of Hartford, Conn., have shown that light can be seen through a clean out opening of not more than one forty-thousandth of an inch. This fact was determined by taking two thoroughly clean straight edges, placing a piece of paper between the surfaces at one end, the opposite end being allowed to come together. The straight edges being placed between the eye and a strong light in a dark room, a wedge of light was perceived from the ends between which the paper was placed and the opposite which were brought together. The thickness of the paper being known the distance apart at the two edges of the small end of the wedge of light was easily calculated, and the result was shown as above.

CARBONIC ACID IN FOGS.—Experiments made by a professor of University College, Dundee, has shown the high percentage of carbonic acid in the atmosphere during fogs. At a time when the fog was densest, eight volumes in 10,000, or more than double the normal amount for the particular locality, was found. In London and Manchester the percentage is much higher. The circumstance thus noted is readily accounted for by the fact that the dispersion of the products of combustion and animal respiration is hindered by the stagnation of the air during the continuance of a fog.

THE MYSTERIES OF NATURE.—The telescope enables us to gaze through the boundaries of the stellar universe; the microscope enables us to look through the stratum of living forms and see the expanse of unappropriated mineral elements. Life even in its minutest forms is superimposed on matter. Strange life! The animalcules a million times smaller than the finest point that can be broken from a cambric needle manifests instincts as remarkable as are observed in higher animals. * * No words can describe, no pencil paint the wonders revealed in a single drop of stagnant water.

BAROMETRIC PLANTS.—A recent little work on barometric plants published in France, gives, among other interesting facts, the following: If the stalks of clover and leguminous plants stand upright, there will be rain; if the leaf of the wood sorrel turns up, it is a sign of a storm, as is also the closing of the convolvulus flower, the expanding of the lettuce flower, and the turning upside down of the flower of the pitcher plant; but if the last named stands erect it will be fine, as it will be if the flower or the sorrel opens.

THE POWER OF LIGHTNING.—It has been calculated that the electro motive force of a bolt of lightning is about 3,500,000 volts, the current about 14,000,000 amperes, and the time to be 1-20,000th part of a second. In such a bolt there is an energy of 2,450,000,000 watts, or 3,284,182 horse-power.

THERE is now being finished at Greenville, Pa., a disc of glass for a refracting telescope lens, which is claimed as the largest that has ever been made in the United States. The disc is 30½ inches in diameter by 5½ inches in thickness, and weighs over 300 pounds.

TO PREVENT the snapping and cracking of radiators when the steam is turned on, the valves being open, it is only necessary to cause the steam to enter slowly, giving the water a chance to escape and the radiator time to warm up.

PHILOSOPHY OF THE ARC LIGHT.—Scientists tell us that the light from the electric arc results from the vaporization of carbon. It is estimated from theoretical grounds that to produce this over 10,000° Fahrenheit is required.

IT has been found, says the *Evening Post*, by careful experiments on plants grown in a confined atmosphere that they abstracted nitrogen from the air around them to the extent of 30 cubic centimeters.

THERE is very little ebb or flow of the tide in the Arctic, but occasionally there are very strong currents. All winter there is a general flow of tide and ice toward the south, while in summer this flow is northward.

OVERHEAD ELECTRICAL TRACTION is meeting with much trouble amid the snow and sleet storms of the East; but such disadvantages are not met with in California outside your highest mountain region.

GOOD HEALTH.

Concerning Cancer.

EDITORS PRESS:—I have read with great interest for several years the cancer discussion, and purported ones of Dr. Cook, which have frequently appeared in the Health Column of your highly appreciated paper, and the fact alone that Dr. Cook is supported by so good and discreet a journal as we all know the PRESS to be is evidence of integrity, good-will to man and that you have no other purpose in view than to put before the world a safe, humane and certain cure for that dreadful malady.

But it looks strange indeed that you should have, as you say you have, within the limits of your wealthy and progressive city of San Francisco 600 miserably afflicted human beings constantly suffering with this dreadful disease; that such an amount of suffering should exist among philanthropists such as the world has never before seen and among that type of men whose very nature has been formed from their peculiar surroundings, and whose first impulse is and always has been to divide the last dollar with a needy fellow-being when such a remedy for so much suffering exists at your very door. Why do those same men stand by and see 20 of this unfortunate 600 die every month when through your reliable and broadly circulated journal you have made it plain to the people of the Pacific Coast that you have a sure and certain remedy for this malady?

It seems to me it would be a far better way to spend some of your surplus money in spreading the news of such a discovery and furnishing the means for its application to the many suffering cancer patients in your city than to expend it on a great institution of learning and science. Why these 600 people suffering with cancer in San Francisco can sit down, or be allowed to sit down, when you claim a positive cure, is more than I can understand.

Take to these sufferers your printed testimonials, giving sex, age, place of birth, present place of residence, when afflicted with cancer, and if same has ever been removed by a surgical operation, and by what physician the diagnosis was made, and prove to those afflicted ones that proper diagnosis was made on those cured by Mrs. Cook, and give names of said physicians and such other information as your own good judgment might see fit; then you will be placing yourself upon a firm foundation, and if Dr. Cook's remedies have merits you will be doing a good work. Great merit in anything or on any proposition should not go begging, and real merit of itself will over-ride anything in the shape of mere prejudice. You have the location and advantage in every way; you have the afflicted ones on whom to bestow your benevolence and wonderful treatment. Cure these 600 cancer-suffering people, or 75 per cent of them, and you need ask for no investigation; the investigation will come. It will come through pure merit and it will be general, and if it comes, my deepest and heartfelt hope is that it will be successful. A constant reader, yours truly, J. C. WOODWARD.

Silver City, March 8, '91.

The writer of the above is one of the firm of Woodward Brothers, founders and machine workers of Silver City, New Mexico. Letters of similar import are constantly being received in this city from various parts of the Pacific Coast and from the East, wherever the MINING AND SCIENTIFIC PRESS is circulated. The same question is also constantly being asked by thousands of people in this city, and much astonishment and no little indignation is being expressed in all quarters at the manner in which the medical faculty of this city, as a body, is steadily ignoring facts which are daily being brought to their notice, and discouraging patients from placing themselves under Dr. Cook's treatment.

We are pleased, however, to state that just at this time there is good reason to believe that proper attention will soon be given to the matter. A petition was sent in to the City Board of Supervisors last week, asking them in view of the large interest which is being felt in this matter by our citizens at large, to make a request of the City Board of Health to appoint a suitable medical commission to make a thorough investigation of this alleged cure, and report upon the same. The Board acted upon the matter promptly, and authorized the Hospital Committee to make the request, and we are assured that that Committee will attend to the duty at once, and we further presume that the Board of Health will lose no time in taking the necessary steps to secure the desired investigation. W. B. E.

Cure for Catarrh.

EDITORS PRESS:—Thinking the enclosed recipe, which proved so valuable to a friend of mine, may be of use to some of your readers, I have copied it as she gave it to me:

"Take one part pulverized saltpetre and two parts pulverized angar. Dissolve one-third teaspoonful in one-third small cup of water and

syringe the nose three to five times a day, according to the severity of the case. Continue for weeks or months if necessary."

Said a lady to me: "I had catarrh in the head so I could scarcely breathe through my nose, and I tried this treatment for several months and it effected a complete cure." It is beneficial sometimes in cases of la grippe.

National City.

ROCK MAPLE

ELECTRICITY.

A DARING PROJECT.—One of the features of the coming electrical exhibition at Frankfort-on-the-Main will be the transmission of power on a scale hitherto never attempted. When it was announced some months ago that it was proposed to transmit 100 h. p. from Lanfen-on-the-Neckar to Frankfort, a distance of more than 100 miles, the statement was received with smiles of incredulity, but now it seems quite probable that not only will the experiment be tried, but that it will succeed in spite of the engineering difficulties that have to be surmounted. The Government has been asked to supply line for the purpose, and on the system used the expense will not necessarily be at all severe, for the use of very high potential alternating currents is the feature of the scheme as at present planned. The alternating generator will supply a step-up transformer that in turn will transmit its secondary current at an enormously high potential along the line, to be re-transformed by a step-down transformer at Frankfort to a potential practicable for an alternating motor. A series of experiments carried out recently at Oerlikon involve the use of pressures as high as 33,000 volts on the line. At such a potential the current transmitted becomes so small that the line is a relatively small factor in the losses incurred, even though it be of the extreme length proposed. Nothing can better illustrate the characteristic advantages of the alternating system than this beautiful process of generating and utilizing currents at a moderate potential, and transmitting them from station to station at a pressure so enormous that the losses in transit become insignificant.—*Electrical World*.

THE FIRST ELECTRIC RAILWAY.—Mr. L. F. Andrews communicates the following to the *Electrical World*: "In your issue of January 31st I find the report of a paper read before the Electric Club of New York by Franklin L. Pope, in which he refers to the probable first electrical motor as being the invention of Thomas Davenport, at Brandon, Vt., in 1835-8. He says that with the aid of another mechanic he made a motor. I desire to confirm Mr. Pope's statement. The 'other mechanic' was Collins Andrews, my father. I well remember the long and vexatious series of experiments made by these two men. The greatest obstacle they had to contend with was the stopping and starting of the motor. It would run when once started by other power, but to get it to start itself was the vexatious point. They finally succeeded, however, and laid a circular track in the shop. On the car was placed a platform or seat to carry one person, and on this I frequently had the pleasure of making the circuit. At that time, at Brandon, was constructed the first electric motor in the United States.

LONG-DISTANCE TALK.—A new land and submarine cable line has just been completed between London and Paris, and a few days ago direct telephonic communication was established between the two cities. The first words over the new line were spoken by the wife of the French Minister of Industry and Colonies, and then a general conversation was held, the line working without any difficulty. The success of this line indicates a future for the telephone which was certainly unsuspected till very recently. It has been believed that only short distances could be covered effectively, and that for remote places reliance must still be had upon the electric telegraph; but if London can talk with Paris over land wires and a submarine cable, it is hardly possible to set bounds to the future of the telephone. Theoretically such will be the case; but in actual practice there are a great many obstacles which it seems almost impossible to overcome, when we pass the thousand-mile post. However, we know that telephony is a progressive science and that great improvements are in store for the future. Who will set bounds to the possible?

THE HORSE-CAR MUST GO.—It is a foregone conclusion that the horse car must go. It is clumsy, slow, uncertain and inadequate. The horse car is unwieldy, and its day of usefulness has gone by. The electric car is being perfected in a manner that invites the confidence of the public. The late severe storm in the East has been an ample test of its power to withstand climatic changes and demonstrated its superiority.

TROLLEY IMPROVEMENTS.—A Western electrician has invented a simple apparatus by which the trolley may be guided without disturbing the connection in cases where changes are necessary. The object is to keep the cars lighted during the operation.

POISONOUS WALL PAPER.—Since the poisoning in the house of the Mayor of Boston has become known, it is said that experts are making it a business to test the wall paper in the houses of nervous people in that city.

ENGINEERING NOTES.

THE LARGEST RAILROAD CORPORATION IN THE WORLD.—The Pennsylvania company's system of railroads is composed of no less than 120 corporations; certainly a colossal aggregation to be under the management of one head. President Roberts in his last annual report says that with few exceptions all these corporations are in good financial condition and are earning fair returns on the capital invested. They represent 7915 miles of railroad and canal, and have a share and bonded capital of over \$700,000,000. They earned in 1890 more than \$133,000,000 gross and moved over 137,000,000 tons of freight and 84,000,000 passengers. In 30 years on the lines east of Pittsburgh & Erie the increase in gross earnings was over 800 per cent and in net was more than 200 per cent. The cost of the securities of other corporations now held by the Pennsylvania was \$113,183,734 and the direct revenue from them last year was \$4,439,404, which is in excess of the total funded debt of the Pennsylvania railroad. In connection with the above figures the report of the London and Northwestern for 1890 is interesting. Its authorized capital is £110,077,934, or, figuring the pound at \$4.85, \$533,877,979. On this the gross receipts from traffic were \$29,651,339 and the net, amounting to \$16,199,117. Dividends at the rate of 4 per cent were paid on the guaranteed and preference stocks and of 7½ per cent on the consolidated stock. The amount of these stocks is £77,107,233. The mileage of the system was 1916½ miles. It will be seen that although the mileage of the Pennsylvania system is 7915 miles, which is just about 6000 miles more than the London and Northwestern, the capitalization of the two companies is by no means so far apart, that of the English corporation being \$533,877,979 against \$700,000,000 of the Pennsylvania. These facts should not be forgotten when the results achieved in both countries are under discussion.

WHAT IS AN "ENGINEER"?—A quiet agitation regarding a narrower limitation to the word "engineer" has again been started in engineering circles, with the prospect that some definite action will be taken in the matter by interested members of the profession. "Engineer" as a term of significance is too ambiguous. It may mean a mechanical draughtsman, a bridge-builder, a patent counselor, a machinist in charge of a stationary engine, a locomotive operator or follower of a dozen other pursuits. The words "locomotive" and "mechanical," for instance, when modifying "engineer," respectively characterize a trade and a profession, a subordinate and his superintendent, yet both are engineers. One or the other should do the graceful thing and yield. If the locomotive engineers are willing to take the initiative they might choose to be called "locomotivists" or "engine drivers," or even "motomeers," the official title of electric operators. But if the professional men should be asked to give up their birthright, what characteristic term could they adopt which would embrace the tri-personality of the mechanical, civil and electrical engineer? It would at best be pseudonymic, for "engineer" should designate the profession and not the trade.—*Railway Age*.

THE SIBERIAN PACIFIC RAILWAY.—The Russian Committee of Ministers, to whom the question was referred, had decided to build the Siberian Pacific Railway within the next six years. The Minister of War has concurred in the above resolution, and Russian engineers rejoice at the prospect of abundant work. The fulfillment of this promise means that a journey of about one month overland will take the traveler from St. Petersburg to Japan. According to the latest accounts, however, the first lines of railway built will only unite existing waterways, leaving the connecting links of rail to be put in later. The west starting point of the system would be at Tomsk, which is now connected by rail with European Russia. The line to Irkutsk, close to Lake Balkal, would be 940 miles long. Another line of about 60 miles would connect the southeast end of the Lake with Zhetysay, on the Amoor river; and 230 miles of rail would connect Srasakajia, on the lower river, with Vladivostok, on the sea of Japan. The total length of rail and water route would be about 5000 miles.

ELECTRIC ROADS IN THE UNITED STATES.—There are now in operation in the United States 260 miles of electric railroads, which is five miles more than those operated by cable. With reference to the mileage of city railroads, it is said that the returns from 286 roads give a total mileage of 3151 miles, which is an increase of 1462 miles since 1880, or at the rate of 146 miles per year. Sixty-one miles are operated by steam on elevated structures and on surface roads. Philadelphia has the largest mileage, 283; Boston next, 200; then follow Chicago with 184; New York with 177, and Brooklyn with 164. Chicago has the greatest length of double track, 176 miles; New York next, 161 miles. The total number of street railroads in independent operation at the first of the year was 807.

THE MANCHESTER SHIP CANAL Co. has expended over \$45,000,000. More money is wanted at once, and it is stated that the City Council of Manchester will advance the \$10,000,000 needed to complete the canal. The

money must be secured by August 15th next, otherwise the men must be discharged and the plant, valued at \$5,000,000, will be idle.

USEFUL INFORMATION.

IS REDWOOD INFLAMMABLE?—Quoth the San Jose Herald: "In protesting against the rate of fire insurance in San Jose, the point that our buildings are almost exclusively built of redwood should not be lost sight of. In cities where pine is used for buildings, the rate of insurance should be far higher than in San Jose for that reason. Redwood is very nearly non-combustible, while pine will burn on the slightest provocation. It is not likely that the committee appointed to present the case to the managers of the insurance compact will forget this point, but it is well to keep it before the public generally, since if we have a local insurance company, we want to make the losses as light as possible, and this can best be done by building exclusively of redwood. The difference between pine and redwood in the matter of combustion has been demonstrated time and again. It is almost impossible to burn a redwood building. If it catches fire, it smolders and chars and is quickly and easily extinguished, while a pine building, once fairly on fire, is doomed to absolute destruction." The story about the uncombustible redwood is a very old chestnut and would be good if only it were true.

NEW USES FOR AN OLD MATERIAL.—Peat, used for fuel from the earliest times, and long known to be of great value as a fertilizer, now finds so many other applications that its preparation has developed into an industry. Peat powder is serviceable, not only about stables but elsewhere, on account of its absorbent and somewhat antiseptic properties and low cost. A few years ago a French surgeon introduced this powder, treated with antiseptic solutions and contained in a cloth bag, as a dressing for wounds. The idea, said to be a very old one among the working people of some places, was improved upon by another medical man of Paris, Dr. Redon, who made a soft and pliable wadding of peat. Other dressings have since crowded these out of hospitals, though the peat applications are coming into use and gaining in favor among veterinary surgeons. Dr. Redon's wadding has yielded important results by leading to many efforts to produce woven fabrics, so that peat is now made into mattresses, coverings, carpets, etc., which are esteemed on account of their power of absorption.

DETECTING OLIVE OIL, BUTTER AND OLEO-MARGARINE.—The reagent employed is a solution of silver nitrate at 25 per 1000 in ethylic alcohol at 95°. About 12 c.c. of the oil in question and 5 c.c. of the reagent are placed in a test tube. The tube is then set in a beaker of boiling water, and the changes of color which take place in the liquids are watched through the glass. Unless the oils are perfectly limpid, they must be previously filtered. Olive oils sooner or later take a fine green color, which is lighter in the superior qualities. Pure cottonseed oil is turned completely black. Oil of earth nuts (*Arachis*) takes first a red-brown color and finally turns green, losing its transparency. Oil of sesame takes a deep red color and remains reddish. Oil of colza takes yellowish-green colors and becomes turbid. Natural butter preserves its natural color. Oleo-margarine becomes a brick red, which color may be detected even in samples containing as little as five per cent of margarine.—*Rauel Brulle*.

SAWDUST seems coming to the front most wonderfully in various ways. The *Brick, Tile and Pottery's Journal* says that a French writer recommends the use of sawdust in place of the hair usually mixed in mortar. He made a composition of two parts sawdust, two parts of lime, five of sand and one of cement, which he alleges is very firm and will not peel off. It also states that the Technical Royal School at Charlottenburg has been making a series of experiments with sawdust, and has now proved that it can be used as building material. The sawdust is mixed with certain refuse mineral products, and compressed with a pressure of 1,500,000 kilograms, to the quadrimeter into the form of bricks. After this treatment, the sawdust forms excellent building material, very light, impervious to wet and utterly non-inflammable. A slab of this substance was placed for five hours in a coal fire, and came out of the test intact.

ENGLISH OPINION.—It is rather satisfactory to learn that British naval architects entertain a good opinion of some of our recent additions to the navy, conceding that they quite equalled and sometimes surpassed European constructions of a like nature. There is no doubt that if Fate should decree that the 7300 ton commerce-destroyer, which Secretary Tracy regards as the ideal naval vessel, six of which could sweep the commerce of any country from the seas, should be constructed at this port, she would make a speed of more than 21 knots and have boilers that would give better satisfaction than some of the cruisers on the other side of the Atlantic have been giving recently.

A TABLESPOONFUL of powdered alum sprinkled in a barrel of water will precipitate all impure matter to the bottom, says the *Pharmaceutical Era*.

Passing Events.

The topic of the day all over the country is the attitude of the Government of Italy toward our nation in connection with the recent occurrences at New Orleans, and the subject is being discussed in all its hearings. Whatever the outcome may be, it will result most probably in more attention being given in the United States to naval affairs and to foreign immigration.

The striking of the gravel channel in the Bald Mountain extension drift mine, Sierra county, is important to that section. Much time and money have been spent in the long tunnel, and every one will rejoice that the persevering miners are about to reap their reward.

The successful manufacture of cement in San Diego county is of great importance to our industrial progress. We now import some three million dollars worth of cement annually to this State. A good lime product is preferable and ought to be cheaper.

The North Bloomfield Mining Co., which was dependent on the famous debris suit, has applied for a modification or suspension of the injunction on the grounds that the conditions of mining are so changed as not to now constitute a nuisance.

New State Laws.

Among the numerous laws enacted by the Legislature, there were very few affecting the mining interests, and still fewer which had any connection with industrial affairs. Of those which will interest the mining and industrial classes may be mentioned the following: Repealing the Act declaring the Klamath river navigable. This is very favorable to the miner of that region of Northern California, where hydraulicking may now be carried on without fear of damage suits. Amending Sec. 394 of the Code of Civil Procedure and providing that when an action is brought by a county against citizens or a corporation in another county the action must be transferred to a county other than the plaintiff. This is known as the Hydraulic Mining bill. An Act relating to and enumerating the navigable streams of the State. An Act providing for the support of the State Mining Bureau. An Act relating to the working of rights of way, the easement of drainage in mines in the State of California.

In addition to these enactments, the Legislature provided for permitting electricity to be used to propel cars through the streets of cities; to include roadways used for traction engines in the provisions of the law of eminent domain; to preserve, protect and improve the Sutter Fort property; authorizing a vote of the people to issue \$600,000 bonds for a Union ferry depot at the foot of Market St., S. F.; appropriating \$300,000 for the World's Fair.

Laws affecting the general interests of the State include one making it illegal to advertise for obtaining divorces, and making train-wrecking punishable by death. There is also to be a Board of Arbitrators to arrange differences between employers and employees.

The semi-annual payment of taxes is now provided for by law. The taxes on all personal property and one-half the taxes on all real property are payable ten days after the second Monday in October, and will be delinquent on the last Monday in November. The remaining one-half of the taxes on real property is payable after the first Monday in January, and becomes delinquent on the last Monday in April. All the taxes can be paid when the first installment is due.

Another measure which should be held steadily in mind provides that at the next general election the people shall vote whether or not the United States Senators shall be elected by popular vote instead of by the Legislature. Recent experience in this State and in other States argues strongly that the present method is wrong in theory and outrageous in practice.

California Cement.

For a number of years we obtained a small amount of cement from Benloia, but the works there shut down a long time since. Then the cement works at Santa Cruz were started, but trouble of various kinds overtook the company and nothing has been done for some years. Now a new enterprise for making cement has been started in San Diego county by the Jamul Portland Cement Works. Considerable money has been spent in the purchase of a plant, gravity railroad, etc. The Jamul Works are turning out 100 barrels a day, but it is proposed to increase this output to the total consumption of California, which at present reaches over 1000 barrels a day. A large force of men is employed at the works, and the deposit of raw material in sight said to be very great.

The use of cement in this State has always been large. The cable railroads alone use immense quantities in constructing their tubes, and we use it very largely for sidewalk and building purposes, in default of cheap stone. For sidewalks in the coast and interior towns, its use is becoming almost universal. We have been importing annually about \$3,000,000 worth of Portland cement, so there is a very good market for the home product, provided its quality is satisfactory. Deposits of the volcanic stone from which this cement is made might be sought for diligently, for they are valuable.

AN ELECTRIC RAILWAY.—Work has been commenced on Stuart and Market streets in laying the roadbed of the S. S. Electric Railway, which will run from San Francisco to Baden, a distance of over 10 miles. When completed, the new road will have connection with the ferries by a switch.

War Ships and Fortifications.

Whatever may be the result of diplomatic correspondence going on between this country and Italy, and the friction between the nations growing out of the New Orleans trouble, there is one thing pretty certain, and that is some war-ships will be built by the United States. It has been difficult for representatives of central or interior States and Territories to see the necessity for coast defenses and first-class war-ships, but the action in the past few days has been humiliated by the knowledge that Italy possesses some 24 first-class vessels of war and we have not a single one to oppose them. We have plenty of cruisers, new and fast, and more being built, but nothing which could meet a first-class modern vessel of war like some of the Italian ships. The fact has also been brought plainly before us that our great maritime cities are ineffectually protected with harbor defenses.

This little "war-cloud" has brought home to us a realizing sense of our deficiencies in the matter of ships and forts. Congress will doubtless proceed at the earliest opportunity to remedy these deficiencies. The nation is rich enough to afford such things and their construction would involve the employment of large numbers of men for some years and the spending of great sums of money among industrial establishments.

Another thing, too, the events of the past week are apt to bring about still further changes in our immigration laws and a closer scrutiny of the class of people coming from abroad to take up their abode with us.

Platinum.

We had a conversation this week with Mr. H. M. Raynor of New York, a gentleman who has for many years been in the business of refining and handling platinum. This metal has advanced quite 100 per cent in price in the last 12 months, and is now worth almost as much as gold itself. The metal sold at \$7.50 per ounce last winter and by May was selling at \$15 per ounce, being even a little higher than that at present. There is a very much increased demand for it, owing to its extensive use in electrical appliances, especially in incandescent lamps. The imports of platinum now amount to about \$900,000 per annum, while it was not so very many years ago that we only imported \$100,000 worth.

There is plenty of platinum in the Ural districts of Russia, and that country has met the increased demand. Still, part of the increase in price in the last 18 months is due to the appreciation in value of the paper rouble of Russia, as we have to pay now a much higher rate of exchange in our purchases of the Russian material.

Another cause for the increase in value is the change in the Russian policy of mining. The platinum was formerly sold as a by-product of the gold mines, but a few years since they began to charge a certain proportion of the expenses of mining to the platinum and it is a by-product no longer.

The Russian metal as it comes from the black sands is in combination with iridium, palladium, osmium and other metals, and when refined only about 80 per cent is pure platinum. That from this coast is, however, still poorer, yielding only about 50 per cent pure metal. It varies in percentage, therefore, as does gold from different localities in its value per ounce.

The platinum from the United States comes from Northern California and Southern Oregon, occurring in the black sands associated with the auriferous deposits. Most of it comes from the black sands of the sea beaches. The supply from here varies greatly in quantity. The miners do not take the trouble to save it that they should, though with this great increase in price it would pay them well to look after the platinum in the sands. The river and gravel miners of the regions mentioned should see to this.

More platinum is obtained out of a given bulk of the Russian than any other. That which comes from South America is better than the California or Oregon product; but at present prices it will pay our gold miners to look after the platinum as well as the gold.

We received in San Francisco last month from the Hawaiian Islands, 87,203,900 pounds of aogor.

The Lick Observatory.

As has always been understood by those who knew of the workings of the Lick Observatory, the maintenance fund is insufficient. Mr. Lick gave \$700,000, and the observatory cost \$600,000, leaving only \$100,000 for its support. This income is entirely inadequate, and the institution has been and is a source of expense to the University of California.

A telescope and set of instruments by no means make an observatory. Skilled assistants are essential. The Lick Observatory has but five observers, while Greenwich has 20, Harvard 36, Leipzig 16, Paris 17, Rio Janeiro 16 and Washington 19. Prof. Holden has addressed the Regents of the university on this subject, calling attention to the necessity of more assistance. He says:

"What is now absolutely required is a photographic assistant of ability who shall also be a skilled astronomer, at a salary of \$1800 per year, and a computer at \$700 per year. A capital of \$50,000 would be required to yield \$2500 of interest, and it is desirable that \$60,000 should be provided, in order to allow for small increases of salary as the assistants become more skilled and more valuable."

The professor hopes that some one of means who has an interest in the great work being done on the summit of Mount Hamilton may make provision for these wants of the institution.

"I have said nothing here," continues Prof. Holden, "of certain hindrances due to our isolated situation or of other work which regularly goes on, such as observations to regulate the clocks and to send out accurate daily time signals; the care of controlled clocks and earthquake instruments in the observatory; the keeping of meteorological observations; the maintenance of our electric lights and batteries, the care and cataloguing of the books of our library; the clerical and mechanical work of a large establishment; the regular reception of 7000 visitors per year; the publication of the work of the observatory; the correspondence which keeps us in relation with other astronomers and helps us to direct the thoughts of hundreds of inquirers and of the members of our Astronomical Society."

The Dodge Improved Rock-Breaker.

One of the heaviest items of expense in maintaining rock-crushers has been that of replacing the jaw-plate. The pin-plates of the Dodge crushers are made of cast-steel, studded with pins of a special steel, which is tempered carefully with reference to their use in the crushers. These pins when first inserted are left flush with the surface of the plates, but the plates, being softer than the pins, wear away more rapidly and leave the pins projecting. Attention is also called to the self-adjusting journal boxes, held in place by steel springs taking up all lost motion in pitman, when the eccentric is worn out of round. These new arrangements common to both Dodge and Grant rock-breakers, not only insure longer life to the wearing parts, but also a more economical application of the power to the work. The improved breaker shown in the cut is especially desirable for fine crushing. The system of construction provides in this breaker for ready positive adjustment for finer or coarser particles as desired. The Parke & Lacy Co. of this city are manufacturers of these machines.

MOLDERS LAID OFF.—The recent action of the Molders' Union in withdrawing its members employed in the Pacific Rollog Mills has been more reaching in its consequences than was at first anticipated. Fourteen union molders were laid off at the Atlas Iron Works, Tuesday, because the foundry can at present turn out no more iron castings for the rolling-mills, where work has been crippled by the strike. The laying off of the molders at the Atlas Works will also throw more than 100 machinists and helpers out of employment. In all, at least 400 or 500 men are affected by the extension of the molders' strike to the rolling-mills.

COAL is reported as having been found on Sutro's land out near the ocean, on the peninsula, and also on the opposite shore of Marin county. But such finds in these localities are apt to "peter out" like the gold discoveries made several times in the same region.

Remarks Upon Judson Dynamite.

[Written for the Press by MARK B. KERR, Member A. I. M. E.]

The Judson Dynamite and Powder Co. has just issued a circular to mine-owners and practical mining men, proposing to put within the reach of every one interested in mining a high explosive at the least possible cost to the consumer. In reading over this circular, sent from the office of the company, 18 California street, it is noted that the stockholders and directors are all men actually interested in the development of the mineral resources of the country.

This organization recalls to mind the recent powder complications in which the other companies, the Giant, the Safety-Nitro, the California and the Vigorite, lately comprised a powder pool called the Associated Powder Companies.

It is not the purpose of this paper to enter into the reasons for the establishment of the Judson Dynamite and Powder Co., the direct cause of the breaking of the powder pool early in January, which has ended in each company acting independently and in its own interest, but rather to mention many new and interesting points that the writer was enabled to glean through the courtesy of Mr. E. G. Lukens, president, and Mr. C. D. Kennedy, superintendent, during recent visits to the new works of the Judson Dynamite and Powder Co. at Nobel, Alameda county, California.

In investigating dynamical geology, one of the most interesting divisions of science, who among us but must of necessity look in silent admiration at those immense volcanic uplifts, which have even recently metamorphosed certain portions of the earth's crust, and torn asunder gigantic fissures, where imagination runs riot in endeavoring to determine the limits of these incommensurable forces. But when a body of men band together to convert into practical use the powers of nature by obtaining a force and attempting to even rival volcanic outbursts, we view their enterprise with admiration, and meet their efforts with encouragement.

Many conflicts have arisen as to the history of the invention of gunpowder, but it is now generally conceded to have originated in the Orient, although there seems no doubt that its introduction into Europe is due greatly to the efforts and experiments of the monk, Berthold Schwartz.

Dynamite is of very recent origin, Nobel, being the first to make practical use of the admixture of nitro-glycerin with infusorial earths which at times is still manufactured, although the present formulae for nitro-glycerin powders differ greatly, being the exclusive property and secret of those manufacturing it.

To mining men, the most interesting point in the manufacture of dynamite is the amount of compression, or the amount of force (expressed in foot-pounds), needed in making a desired compression. The principles and instruments in use by the Judson Co. are much the same as those described by Lieut. W. R. Quinan in his able report on Vigorite powder, but to enable the reader to obtain a clear idea of the methods, the following description is given:

The instrument (Fig. 1) consists of a large cast-iron block, the size of an ordinary blacksmith anvil. A rectangular hole is cut through this block of sufficient height to readily slide in and out, the leaden plug (L). A platen, resting on the plug, projects above the top of the machine (P). The charge of dynamite to be tested is put upon the platen, and upon this is placed the weight or shot, through which is run a fuse with a fulminating cap (W). When the powder is detonated, the weight is blown off and the lead plug compressed. The plug is measured before and after compression, and the difference is expressed in inches.

Fig. 2 shows the plug before and after compression, with 60 per cent dynamite.

The following figures give average compressions of both a low-grade dynamite (Triumph) and of a high-grade (60 per cent Judson dynamite) expressed in inches:

Original plug.....	1.000
Size after compression (5 per cent dynamite).....	0.620
Amount of compression.....	0.380
Original plug.....	1.000
Size after compression (60 per cent dynamite).....	0.360
Amount of compression.....	0.640

In noting this result, the compression of the 5 per cent is seen to present a greater proportional average than the 60 per cent, which shows the superior quality of this new low-grade powder. The compression of the high-grade (60 per cent) would be much greater, but the increasing diameter of the plug, caused by the high explosive, must be taken into account in averaging results. Liquid nitro-glycerin gives a compression of .950 of an inch, so that the above seems a fair test. The amount of dynamite used is always one pennyweight.

By simply arranging these results and obtaining a scale for the force, a table is readily made giving compression (in foot pounds) of any grade of dynamite powder.

The Triumph (a dark brown powder) will be especially useful in removing stumps and in

FIG. 1—INSTRUMENT FOR MEASURING COMPRESSIONS.

FIG. 2—PLUG BEFORE AND AFTER COMPRESSION.

certain character of rock work and in tunnels, where the gases generated being smaller, the comfort of the miner is comparatively greater.

During my visit many other points concerning the Judson dynamite powders were noted, viz.: The various grades from 20 to 60 per cent being tamped in paper cartridge pack solidly; the Triumph, however, being used for lighter work is generally packed "in bulk."

Experiments made in recovering the acid needed in the manufacture of these explosives

very much in favor of these large companies, affording a fair remuneration to the inventor as well as reflecting credit to the State where the equable climate is advantageous to experimentation. In the coolness of the early morning, the nitro-glycerin is prepared, and during the heat of the day the powder is mixed, tamped and boxed.

A compound prepared under such advantageous circumstances must of necessity be uniform in quality, and thus the moral responsibility of the manufacturer is decreased, and he

THE CHOCO, OR CHAYOTA, AS GROWN IN SANTA BARBARA.

have given encouraging results, and at present writing most of the sulphuric acid and a fair percentage of nitric acid is recovered by means of new methods.

In conclusion, it would seem to an observer that California is making and has made rapid strides to the front in the manufacture of high explosives, and that the elements of success are

can safely engage in such a work without running great risks or sacrificing human lives.

The future of the powder industry on this coast is in its infancy, and before long we may look to see this trade extended, especially encouraging since the large capital which has been invested in these new works, notwithstanding the great competition existing. When neces-

sity demands, competition with other countries will begin in the manufacture of a high quality of sporting powder used now in our own munitions both by land and by sea, besides affording aid to the pioneer in his land clearing, the miner in his work with pick and shovel, and the engineer in rock excavation and tunnelling.

A New Food Product.

[Written for the Press by DR. LORENZO G. YATES, F.L.S.]

The Choco Plant (*Sesuvium edule*).—This plant, which has been introduced into cultivation in Florida, where it is growing in favor, and is, perhaps, better known there than elsewhere in the United States, is being tested in Santa Barbara county by Mr. Kinton Stevens of Montecito, who obtained the seed from Samoa, and has one very thrifty vine that promises a large yield of the curious squash-like fruits. *Sesuvium edule* is the botanical name of this plant, but it is perhaps better known as "Choco," "Chocho," "Chayota," and "Portuguese Squash." It belongs to the order Cucurbitaceae, and is a perennial vine, resembling in growth and fruit our summer squash or vegetable marrow. It is a very prolific bearer. Both the fruit and the great yam-like tuber are used as food by man and beast in the West Indies, where it is considered a wholesome article of diet. The roots often weigh as much as 20 pounds. They have a flavor similar to the yam, and are considered a greater delicacy than the fruit which in a raw state resembles the chestnut in flavor, and under favorable conditions weigh over three pounds.

A few of these plants, which in our dry seasons could be easily supplied with water, would furnish a family with an abundant supply of food, and such valuable food plants should be cultivated all over the State, as is being done by the Government in India as a provision against famine in dry seasons and failure of other crops.

Although a native of Tropical America, judging from the plant I saw, it does not seem to be particular as to soil nor require special care.

One peculiarity is that the fruits sprout while growing on the parent plant. The proper way to grow them is to plant the whole fruit, as they have but one seed, and they produce fruit in three months under favorable conditions.

In an illustrated report of the Botanic Gardens of Bangalore, India, there is a figure of the fruit of this plant, but it does not show the sprouting of the fruit, which is shown in the accompanying illustration made from the plant grown near Santa Barbara, nor is this peculiarity mentioned in any publications which have come to my notice; whether this is its normal habit or is due to climatic conditions, I am unable to state. It may arise from the fruits being left too long on the vine; it would probably be advisable to pluck them before they sprout.

Santa Barbara, Cal.

[Our engraving is made from an excellent sketch of the fruit and vine made by Dr. Yates. EDS. PRESS.]

Mining Bureau Museum.

Following are among the recent contributions to the California State Mining Bureau:

Building stone—Shasta county; from the Cal. Sandstone & Contracting Co.

Hematite—Breitung mine, Tower, Minnesota.

Fifteen specimens various minerals including syenite, quartzite, gabbro, breccia, greenstone, etc. from the Lake Mine, Minnesota.

Felsite—Red—From the great Palisade, Lake Superior.

Quartzite—Red—Seskiwith point, Isle Royal, Mich.

Trap—Basaltic, Graod Marias, Minn.

Copper ore—Epiclote, Saginaw mine, Isle Royal, Mich.

Iron Ore—Vermillion lake, Minn.

Auriferous gravel—Mayflower mine, Placer Co., Cal.; D. M. Kent.

Embolite (chlorohomide of silver in cerussite)—Central mine, Broken Hill, N. S. W., Australia; W. N. Folger.

Cerussite (carbonate of lead), with embolite, from same mine.

Silver—Native on pyrrargyrite sulph-antimonide of silver, with azurite and malachite; Broken Hill mine, Australia.

Confederate currency, Mrs. S. B. Hayden.

Talanite-sphene (silico-titanite of calcium)—Renfrew Co., Ontario, Canada; D. R. McKillican.

Stalactites—Mammoth Cave, Kentucky; A. S. Penfield.

Quartz with gray copper, carrying two ounces gold and two ounces silver to the ton—Buster mine, Idaho; S. W. Smith.

Quartz carrying \$100 gold per ton—Cleveland mine, Idaho; S. W. Smith.

The Bureau has also received a number of choice specimens from the Technological Museum of Sydney, N. S. W. Among them are three specimens of gold-bearing quartz from the Peak Hill gold field, and six samples of ore from the Broken Hill Proprietary Co.'s property, one of the greatest mines in the world.

One of the most interesting specimens in the collection is a sample of coal containing fossil resin, something rarely found in coal.

Three casts of gold nuggets come with the collection, one of which in the original was valued at \$4420 sterling. This nugget has been dubbed the Viscount of Canterbury and was found but 15 feet underground at John's Paddock, Berlio, Victoria.

A New and Splendid Companion to all the Metal Industries.

Fully abreast of the latest inventions and discoveries, as well in the largest and coarsest as in the smallest and finest of metal work.

MINING

—AND—

Ore Dressing Machinery.

By C. G. WAMFORD LOCK.

CONTENTS.—Motive Power—Transmission of Power. Quarrying—Prospecting, Shaft-sinking, Coal-cutting, Pumping, and Ventilating Machinery—Lighting—Hauling and Hoisting Machinery—Reducing—Dressing—Miscellaneous.

Price \$21.00. Circulars and Catalogues on application.

E. & F. N. SPON, Publishers,

12 Cortlandt St., New York.

The instrument represented in the above cut is a new and grand little invention, being designed to save life and limb, and innumerable lawsuits, by doing away with the dangerous operation of digging out wet and unexploded loads where Giant Powder is used in mining. The little instrument crimps the cap on to the end of the fuse firmly and absolutely water-tight. It is also used for cutting the fuse. They are neatly gotten-up of the finest cast steel, nickel plated. Price, \$2 each, or the entire instrument finished in gold plate, \$5.

**JAMES LEFFEL'S
Mining Turbine Water Wheel.**

These Wheels are designed for all purposes where limited quantities of water and high heads are utilized, and are guaranteed to give more power with less water than any other wheel made. Being placed on horizontal shaft, the power is transmitted direct to shafting by belts, dispensing with gearing.

Estimates furnished on application for wheels specially built and adapted in capacity to suit any particular case.

Further information can be obtained of this form of construction, as well as the ordinary Vertical Turbines for Wooden Penstocks and in Iron Globe Cases, free of cost, by applying to the manufacturers.

American and Foreign patents issued, and general patent business for Pacific Coast (more transacted with perfect security, at reasonable rates, and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s Scientific Press U. S. and Foreign Patent Agency, the following are worthy of special mention:

ILLUMINATING PANELS IN CONCRETE FLOORS.—E. L. Ransome, S. F. No. 448,993. Dated March 24, 1891. This invention relates to improvements in illuminating basements and chambers beneath concrete flooring, and it consists especially in placing the glass directly into the concrete. In placing the glass in concrete flooring for illuminating basements or for dark chambers beneath such flooring, it has been customary to fix the lights in iron or metal plates or frames perforated to receive and hold them in position, and these frames have been set into the flooring, either before or after it was built, so that a joint would exist between the lights and the floor itself, and these joints are difficult to make tight. In Mr. Ransome's improved method he reduces the cost of manufacture, and does away with any joints between the glass or illuminating tile and the main floor, by fixing the illuminating glass or tiles directly into the concrete floor in the process of manufacture, and dispensing with all metal frames or supports preventing any difficulty with joints by moulding the glass directly into the floor itself when it is being built.

SWINGING HOSE REEL.—Wm. F. Bowers, S. F. No. 449,033. Dated March 24, 1891. The invention relates to that class of hose-reels which are secured to wall and are so mounted as to swing, suitable joints being provided to allow the uninterrupted flow of the water, no matter to what position the hose may be turned. The object of the invention is to produce a simple and effective hose-reel of this class.

SWITCH STAND.—John H. Wallace, S. F. No. 449,017. Dated March 24, 1891. This invention relates to that class of switch-stands designed to hold and lock railroad switches and yet permit the movement of the switch-rail, when locked, to move past the yielding resistance away from its adjacent rail to enable the wheels of cars to pass through the locked switch, without leaving the main rail, the point springing back to its place when the wheels have passed through. The invention consists of certain devices and details of construction designed to improve this class of railroad appliances.

PORTABLE ELEVATOR.—Nicklaus Anderson, S. F. No. 449,026. Dated March 24, 1891. This improvement in elevators consists of a framework mounted on wheels, so as to be transported from one portion of a warehouse to another, vertical guides made adjustable in height, a platform suspended so as to travel between the guides, and a means for raising and lowering the platform. This elevator is especially designed for use in houses where grain or other substances are to be stored and where it is necessary to transport the material over the floor and then lift it to a considerable and varying height to reach the point of storage.

Don't Fail to Write.

Should this paper be received by any subscriber who does not want it, or beyond the time he intends to pay for it, let him not fail to write us direct to stop it. A card (costing one cent only) will suffice. We will knowingly send the paper to any one who does not pay for it, but if it is continued, through the failure of the subscriber to notify us to discontinue it, or some irresponsible party requested to stop it, we shall positively and without delay pay for the time it is sent. LOOK CAREFULLY AT THE LABEL ON YOUR PAPER.

The new coast defense vessel Monterey, now being built at the Union Iron Works, is being rapidly pushed to completion. It is expected to be ready for launching in about six weeks.

Assessment Notices.

INYO MARBLE COMPANY.—LOCATION
of principal place of business, San Francisco, California.
Location of works, Keeler, Inyo County, California.
Notice is hereby given, that at a meeting of the Board of Directors, held on the 30th day of March, 1891, an assessment (No. 12) of Ten Cents per share was levied upon the Capital Stock of the Corporation, payable immediately to United States gold coin to the Secretary at the office of the Company, 132 California street, San Francisco, California.
Any stock upon which this assessment shall remain unpaid on the 12th day of May, 1891, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on FRIDAY, the 24th day of May, 1891, to pay the delinquent assessment, together with the costs of advertising and expenses of sale.
By order of the Board of Directors.
G. W. LUCE, Secretary.
Office, 132 California Street, San Francisco, California.

Dewey & Co.'s Scientific Press Patent Agency.

OUR U. S. AND FOREIGN PATENT AGENCY presents many and important advantages as a Home Agency over all others, by reason of long establishment, great experience, thorough system, intimate acquaintance with the subjects of inventions in our own community, and our most extensive law and reference library, containing official American and foreign reports, files of scientific and mechanical publications, etc. All worthy inventions patented through our Agency will have the benefit of an illustration or a description in the MINING AND SCIENTIFIC PRESS. We transact every branch of Patent business, and obtain Patents in all countries which grant protection to inventors. The large majority of U. S. and Foreign Patents issued to inventors on the Pacific Coast have been obtained through our Agency. We can give the best and most reliable advice as to the patentability of new inventions. Our prices are as low as any first-class agencies in the Eastern States, while our advantages for Pacific Coast inventors are far superior. Advice and Circulars free.

THE GIANT POWDER COMPANY

Manufacture Three Kinds of Powder, which are acknowledged by all the Great Chemists of the World as

The Safest and Strongest High Explosives in the Market.

GIANT POWDER or DYNAMITE,
Of Different Strengths as Required.

NOBEL'S EXPLOSIVE GELATINE," which contains 94 per cent of Nitro-Glycerine, and GELATINE-DYNAMITE, Stronger than Dynamite and even Safe in Handling.

JUDSON POWDER IMPROVED.

FOR RAILROADS AND LAND CLEARING. Is from three to four times stronger than ordinary Blasting Powder, and is used by all the Railroads and Gravel Claims, as it breaks more ground, pulverizes better and saves time and money. It is as dry as the ordinary Blasting Powder and runs as freely.

BANDMANN, NIELSEN & CO.,

OAPS and FUSE for Sale

GENERAL AGENTS, SAN FRANCISCO CAL

The Explorers' and Assayers' Companion.

A Third Edition of selected portions of the "Explorers', Miners', and Metallurgists' Companion."

A practical exposition of the various departments of Geology, Exploration, Mining, Engineering, Assaying, and Metallurgy.

Price, \$8.00 post-paid. Sold by DEWEY & Co., Publishers, 220 Market St., San Francisco.

By J. S. PHILLIPS, M. E.

The work is divided into four parts—Rocks, Veins, Testing and Assaying. The geological chapters are intended to give miners a practical idea of the various formations. The chapters on mineral veins are derived from long observation, and the section on exploration has been carefully considered. All that relates to discrimination and assay of minerals has been kept as free from formulae as possible. The work is written for practical men, and all the explanations and descriptions are clear and to the point. It is so prepared that it is useful to uneducated men as well as scientists.

Books on Working Ores.

By GUIDO KUSTEL, M. E.

ROASTING OF GOLD AND SILVER ORES (Second Edition) and the Extraction of their Respective Metals without Quicksilver. By GUIDO KUSTEL, M. E. 1880.

This rare book on the treatment of gold and silver ore without quicksilver is liberally illustrated and crammed with full facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe, and the why and wherefore. It contains 156 pages, embracing illustrations of furnaces, supplements and working apparatus. It is a work of great merit, by an author whose reputation is unsurpassed in his specialty. Price, \$3, cloth, postage free. Sold by DEWEY & Co., Publishers, 220 Market St., San Francisco, Cal.

By C. H. AARON.

AARON'S LEACHING GOLD AND SILVER ORES, the most complete hand-book on the subject extant; 164 pages octavo. Illustrated by 12 lithographic engravings and four wood cuts. Fully indexed. Plainly written for practical men. In cloth, \$3. Sold by DEWEY & Co., S. F.

CAPACITY, 12 Tons in 24 Hours. 3 H. P.

MARSHUTZ & CANTRELL, Sole Manufacturers.

The Patentees and Manufacturers cordially invite miners to critically examine and pass judgment upon this improved system of milling and amalgamating ores in the following particulars:

1. The cost is less than one-half of stamps of same capacity.
 2. The freight to mine is less than one-half of stamps.
 3. The cost of erecting is less than one-fourth of stamps.
 4. The power to drive it is less than one-half of stamps.
 5. The wear is less than one-quarter of stamps.
 6. There is no wear except on shoes and dies.
 7. In point of amalgamation it is superior to any other machine in use.
 8. In its simplicity of construction.
- We challenge competition with Stamps, Ball Pulverizers or and other ore crushing machines now before the public.

Send for Circulars and Price List.

IMPROVED BELT FRUE ORE CONCENTRATOR.

The Best Ore Concentrator in the market, having double the Capacity and doing its work as close as the plain Belt machine, while its concentrations are clean. It is used in number of Mills, the most notable of which is the Alaska M. & M. Co's Mill, where 24 Improved Belt Frues are taking the Pulp from 120 Stamps, crushing 350 tons per day, and is giving entire satisfaction as against 48 plain Belt Machines, taking the Pulp from the other 120 stamps.

Price of Improved Belt Frue Vanner, \$825, f. o. b.
Price of Plain Belt Frue Vanner, \$575, f. o. b.

For Pamphlets, Testimonials and further Information apply at office.

ADAMS & CARTER, Agents FRUE VANNING MACHINE CO., Room 15, No. 132 Market Street, San Francisco, Cal.

Protected by Patents December 22, 1874; September 2, 1879; April 27, 1880; March 22, 1881; February 20, 1883; September 18, 1883; July 24, 1888. Patents applied for.

There are Over 2200 Plain Belt Machines now in Use.

THE MONTANA COMPANY (Limited), LONDON, October 8, 1885.
DEAR SIR:—Having tested three of your Frue Vanners in a competitive trial with other similar machines (Triumph), we have satisfied ourselves of the superiority of your Vanners, as is evidenced by the fact of our having ordered 20 more of your machines for immediate delivery. Yours truly, THE MONTANA COMPANY (Limited).

N. B.—Since the above was written the 20 Vanners, having been started, gave such satisfaction that 44 additional Frues and more stamps have been purchased. ADAMS & CARTER.

"TRIUMPH" ORE CONCENTRATOR WITH IMPROVED RIFFLED BELT.

The competitive trials which have been held between the "Triumph" Ore Concentrators, the "Frue" Vanners and other forms of concentrating devices, do not warrant the assertion that the "Frue" Vanner is the best ore concentrator in the market. The fact that the "Frues" have improved (corrugated) belts does not militate against the superiority of the "Triumphs"; for, when desired, they (the "Triumphs") can be mounted with a superior belt known as the "Blasdel" Riffled.

Price "Triumph" Concentrators, with Improved (Patented) Belt - - - \$650 f. o. b.
Price "Triumph" Concentrators, with Plain Belt - - - \$550 f. o. b.

We are prepared to guarantee the superiority of the "Triumph" over the "Frue" or any other form of Concentrator, for coin it need be. Circulars and testimonial letters furnished on application.

(PATENTED.)

Both the "Triumph" Concentrator and "Blasdel" (riffled) Belt are protected by incontestable letters patent, granted by the Government of the United States.

GRASS VALLEY, NEVADA CO., CAL., Nov. 10, 1885.

Joshua Hendy Machine Works, 39 to 51 Fremont St., S. F., Cal.

GENTLEMEN:—I am pleased to state, in reference to the "Triumph" Ore Concentrators, that four (4) of them were placed in the mill of the Original Empire Mill and Mining Company in April, 1884, and a thorough test made of their practical operation; and their efficiency having been demonstrated, four (4) more were subsequently introduced as the complement of the Twenty (20) Stamp Mill, and the eight (8) have been and are now running with entirely satisfactory results.

At the Ten (10) Stamp Mill of the North Star Mining Company, under my supervision, four (4) are also in successful operation, and from my observation of their practical workings, I am convinced that this form of Concentrators is the equal, if not superior to any other style of Vanners or concentrating devices.

[Signed] Sup't North Star and Original Empire Mining Co.

N. B. When the stamping capacity of the two above named mills was increased, more "Triumph" Concentrators were purchased, and twenty-eight (28) are now in constant successful operation.

CORRUGATED ROLLS.

PLAN OF CORRUGATED ORE ROLLS.

Rolls for Ore.

On page 145 of the MINING AND SCIENTIFIC PRESS (March 7, 1891) we illustrated a high-class dry-crushing set of rolls for ore. On this page the engravings show a cheaper form of crushing rolls. These are chiefly adapted to comparatively coarse work, but can also be used for tolerably fine crushing when the rolls are in good condition and the shells are new and of good material. They are not, however, so well adapted to withstand continuously the heavy strain incident to fine crushing as the high-class rolls previously illustrated.

These rolls are also driven by pulleys on each roll-shaft, without the use of gearing.

The corrugated rolls, herewith illustrated, where large quantities of material from a rock-breaker are required to be crushed to a size of about three-quarter inch, give excellent results when well made and adjustable with reference to uniform spacing of corrugations on opposite roll-shells. They also crush the material to the same degree of uniformity as the smooth rolls, and with very little sliming. These rolls are manufactured with a patented appliance for perfect adjustment, so as to obtain uniform width of space between roll-shells for all posi-

tions during rotation. The roll-shells are made of mild cast steel, and wear a long time before requiring to be replaced.

These rolls are particularly adapted to the second crushing of galena and all ores where a gradual reduction in size is advisable. These forms of rolls, as well as those previously illustrated, are manufactured by the Fulton Iron Works of this city.

TIN.—It is stated that the unselected ores of the Cajalco tin mines, San Bernardino county, yielded at the test run over ten per cent of metallic tin. The present openings in the

PLAN VIEW OF CORNISH ROLLS.

CORNISH ROLLS.

Cajalco mine alone will give a daily output of 100 tons of ore. A large mill and reduction works for working 200 tons per day will be ready for work by June 1st.

DARBY & LAYDON have been awarded, by the Harber Commissioners, the contract for building the first mile of the belt railroad. The price is \$36 775. Work is to be commenced in 30 days and completed in 60.

A franchise has been granted for a double-track railway from San Jose to Alum Rock point, to be operated by Hoskins electro-vapor engines.

CORRESPONDENCE.

We admit, unadvised, opinions of correspondents.—E.D.S.

Loss of Gold.

Practical Tests in Milling the Gold Bearing Rocks.

[Written for the PRESS by ALMARIN B. PAUL.]

It is not an assumption to say that in the past 25 years I have written more on the wastage of the precious metals than any one of my time, at least, within my knowledge. Yet others realize the fact and have done good work in the same direction; notably for California, Henry G. Hanks, Melville Atwood and Louis Blanding. I have written so much on the subject that it may be considered an injury to me, as many deem it a hobby rather than the emanation of deduced facts. There are many writers on the subject of gold, and many assert the fact of a loss, but their declarations are too often assertions, without being supported by actual tests of their own making. Yes, I have written much and expended no small amount of money and time to find out facts about which men who do not spend their time and money do not get at, but think are not so. They are content with the "think," I have shored to know. A man whose life has been spent among the rocks and metals cares but little for the "think" of mankind, and that's my case. To say that silver milling is far in advance of gold milling, with all its improved appliances, is stating a demonstrated fact, too plain to be doubted by those who have had experience in working the two metals. The assertion may be doubted by some who will try and upset the position by asserting that gold has nearly double the specific gravity of silver, consequently it should settle and be taken up more readily, but this is false reasoning, when applied to the bulk of gold-bearing rocks. There are other questions that must be considered. 1st, the atomic character of gold in its matrix; and 2d, the envelopment of rebellious substances. Although my tests heretofore have been many and varied, yet the past year has enlarged my knowledge of loss, and which has increased the wonder that so few give heed to so important a matter, and do not seek to benefit themselves by closer investigation and more careful manipulation.

To overcome this loss has been my earnest study for many years, and to a very great extent I have succeeded. That there is an incredible amount of gold that from various causes float, and is carried off with the water over all machinery, that can be placed to retain it, and which will move on as long as there is the least density of water or agitation of it, I see and know. Some will explain, "we all know that," but the extent of this loss value, the great body of miners do not know.

A very great loss is made from several facts: 1st, the great value of all gold-bearing rocks is in very fine gold; 2d, that you are never satisfied with your milling results when compared with your assays or "think" value; 3d, that failure after failure occurs on good properties because they do not save the metal; 4th, that a rush of water exerts a power to wash off the sands and why not the gold?

It was only a few months ago you published an article from an English writer on the subject of imperfect milling of gold rock, and who asserted that from the civilized world came the same story. I am firmly of the opinion that the free gold product of the majority of all the gold mills, in all our States and Territories can be doubled. This belief is founded on the fact that in all my larger or smaller tests, I never failed in doubling the yield, and in the majority of instances have exceeded it, when testing by the dry way. A friend at my elbow says: "what is the use of your writing these articles?" millmen will not heed them, and why give your knowledge and tests away? While I admit there is force in the observation, yet the gold fields are extensive enough for us all, and my work may be a benefit to some one if not to myself. I cannot but think, however, that it is fooling away time to write these articles, as few believe, and so few heed the assertion of facts made by others, when not in accord with their own ideas; but to the public the ideas go for what they may choose to place upon them. You have the labor and thoughts at no cost to you, and it is for you to seek the truth of them to gain the profit.

As a verification of these ideas of loss, I will here give a few important tests which may be of interest to some of your readers.

One of the tests having a good lesson in it, was the taking up of a given quantity of tailings, water and all, after it had passed from the battery over silver plates, and blanket concentrators, and then over 60 feet of riffles. Water tailings, etc., by measurement, passed off at the rate of 20 gallons per minute. This bulk of material was allowed to rest for 24 hours before the water was drawn off for drying the residue. The tailings were then carefully dried, sampled, and assayed, with the result of \$7.80 per ton. The material was then charged with clear water, and agitated so as to produce what we recognize as muddy water from the batteries. This was then drawn off free of any grit of the tailings, and was also allowed 24 hours for settling, when it was drained, dried, sampled, and assayed, with a result of \$3.65, and this on what could not be considered over \$15.00 rock, as the highest

estimate of its value. The figuring on this test can be summed up as follows: There was passing off from the batteries every 24 hours, 28,800 gallons, a loss of about 1/4 of a cent per gallon of water and tailings, equaling \$72 per 24 hours, an amount a small fraction less than \$5 per ton for quantity worked, and this after the sulphurets had been taken up.

For another test, 100 tons of rock were crushed by the battery, without regard to amalgamation, either in the battery or on silver plates, or concentrating the sulphurets. The material as crushed passed to a tank (No. 1), from No. 1 to tank No. 2, from No. 2 to tank No. 3 (now as muddy water), from No. 3 to tank No. 4, from No. 4 to No. 5; the water from No. 5 was then used as required by arrastras. Tanks No. 1 and No. 2 were not sampled, as they contained the bulk of the material and value for working in arrastras. Of all the rock crushed, about 16 per cent passed into tanks Nos. 3, 4 and 5; these were carefully sampled and assayed, with the following results: Tank No. 3 gave \$5 per ton. Tank No. 4 gave \$4.85 per ton. Tank No. 5 gave \$3.40 per ton. Muddy water taken from the pipes gave a residue, after evaporating the water, that assayed \$3.30 per ton. Of course there was but very little of this, yet enough to show that gold was still passing on. The size of the above tanks averaged about 250 cubic feet each.

This test was on what was considered low-grade ore; on higher grade, no matter how free the gold (say \$12 to \$20 and higher), the loss in muddy water would be possibly equal to the amount saved by the best manipulation, by battery and silver-plate working, wet. Of course this cannot apply to what may be considered grain gold or specimen rock.

Another lot of over 200 tons, crushed by battery, with all ore run into tanks for arrastra working, and having the muddy water passed on into two other tanks, each 8x17.3 feet deep (inside measurement), gave an interesting lesson as follows: From tank No. 1, receiving the muddy water, it flowed into No. 2 at the top of tank. Taking the two tanks, there was retained 16 per cent of all material crushed, tank No. 2 having one-third of tank No. 1.

The value of tank No. 1 showed by assay that it contained 15 per cent of the full assay value of the material crushed, while tank No. 2 gave 12 per cent, leaving off fractions.

Another very surprising, and yet very practical test, is the following: I took 90 tons of ore for working, part by battery and silver-plate amalgamation, then concentrating on blankets, part by arrastras, wet working, but with the ore crushed dry.

Then 30 tons by dry reduction and dry amalgamation, with the following results: The battery and silver plates gave a yield of \$9.4 cents in free gold per ton, with concentrations not exceeding \$2.50 per ton of ore reduced, making a total of say \$3.10 per ton. The dry ore worked by arrastras wet, gave in free gold a yield of \$6.46 per ton.

The 30 tons worked by dry reduction and dry amalgamation gave \$3.36 per ton in free gold.

A whole page I could fill of similar tests, but these alone should settle in the minds of all that the wastage of gold by our general wet working, slashing system is enormous when we consider the great number of mills thus operating in all the States and Territories.

I do not say that on all ores the same results would be obtained, but in proportion as is the per cent of atomic gold will be the per cent of loss. When I assert that it is my opinion one-half of the free gold is washed off by the slashing battery wet process, taking all the gold-mills as one, you will see I have much for backing that opinion, for these, as puzzling as it may seem, are cold figures and solid facts.

Taking an experience of over 40 years in mill working for gold, I must say that I am clearly convinced of the following facts:

1st. That all gold rock for gaining a proper percentage should be pulverized dry no matter how treated afterward.

2d. That dry amalgamation is the most perfect of all systems of amalgamation.

3d. That where water is used, slow-motioned arrastras are the most efficient amalgamators.

4th. That take the general run of gold rock, the arrastra is the most profitable. On high-grade rock, carrying fine gold, the dry way is most profitable.

It is these convictions that have forced upon my mind, the effort and labor of perfecting both plans.

As before stated, I say to the miner, you have the labor and thoughts at no cost to you, and it is for you to seek the truth of them to gain the profit.

Ophir, Placer County.

[From Our Traveling Correspondent.]

EDITORS PRESS:—The Eclipse mine, which started off with most flourishing prospects, has been attached and at the present time is tied up.

The Hathaway

Is owned by Messrs. Valentine Broa, G. F. Taylor superintendent. At present the mill is shut down while the shaft is being put down to 350 feet. This will give the mine 150 feet of new stops. The shoot has been worked for a length of 1116 feet, the vein carrying an aver-

age width of 2 1/2 feet of quartz that goes from 2 to 3 1/2 per cent in sulphurets of a value of \$125 to \$175 a ton. The vein matter averages \$7.50 in free gold, while the total value saved out of the quartz is \$9 a ton. The ores of the section are such that a good percentage of the ore's value escapes in working. The Hathaway will start her stamps to dropping about the middle of April.

Gold Blossom.

E. L. Hubbard and C. F. Reed are owners of this mine. It is located about 1 1/2 miles west of Ophir. The main shaft is down 210 feet, with two drifts of 150 feet each. The vein averages three feet in width. The quartz carries three per cent of sulphurets that go \$250 a ton, while the average value of the ore is \$25. Of this but about 25 per cent is saved, making the mine a three-foot vein of \$6 ore. The mine has a ten-stamp mill with concentrators. The property consists of four locations, or 6000 feet on the vein. Half a mile east of the mill a cross-cut tunnel has been run that cuts the vein 100 feet. The vein is being drifted upon at this point. The ore is of the same character as in the shaft and the vein is four feet wide.

Boulder.

J. B. Brown, F. and J. Kaiser and Dr. M. Schnabel are owners of this mine. The property covers 1000 feet on the vein. The shaft is now down 112 feet and a drift run 180 feet on the vein to connect with and drain the shaft.

The average width of the vein has been 3 feet of quartz; 300 tons have been milled that gave an average of \$6 a ton in free gold. In addition to this the vein carries one per cent of sulphurets that go \$300 to the ton.

The bottom of the shaft is in very rich rock. Three-fourths of this mine will be sold for less than the value of the ore in sight. There is no boom in Ophir, but the promise of steady, quiet, successful mining. The work of the past was in the rich pocket leads; that of to-day in the milling ore veins that were discarded in the past. The Hathaway has shown that the vein goes down, the ore bodies are long and of good grade and veins of sufficient size to make their working profitable.

E. H. SCHAEFFLE.

Placers in Sonora, Mexico.

EDITORS PRESS:—Much interest has been manifested, among vein and placer gold miners, in the interesting accounts you publish, from time to time, of the successful extraction of gold by the miners in Southern Africa, as well as in Australia.

To the mind of most American miners, these are remote localities, expensive to reach, and under Governments so dissimilar to our own that the temptation to American venture and enterprise in either of the above regions is very slight indeed.

With this in view, and the gradual lessening of the gold returns from California, I have thought that some accounts of mines and placers nearer home might not be uninteresting to your many readers, particularly if located in a country not subject to the ban laid upon the State and most of our hydraulic miners by the "Debris laws."

I write this from personal experience alone, and shall advance but little of history and tradition, and then only desire them to be taken for what they are worth.

In the northwestern part of the State of Sonora, Mexico, and southerly about 15 leagues from the city of Altar of that State, lie the great gold placers of Los Llanos and La Cienega. Briefly, the discovery of these placers was made, in the year 1803, by Don Teodoro Salazar, with a party of soldiers, while in pursuit of hostile Indians who had been depredating among the cattle ranches in the vicinity. Gold was found in great abundance scattered over and among the sands that covered the ground of the gradually sloping plains lying at the base of the mountains of San Francisco, whose trend is almost due east and west, that of the placers being due north. The gold first taken from the plains was in size like grains of corn and from that to hickory nuts, the "chispas" ranging sometimes much larger, authentic accounts describing some to weigh as high as 25 pounds.

The extent of the placers of Los Llanos was about 3x4 leagues, and one can readily imagine that they were soon the scene of a busy population running well up into the thousands. The one great drawback, though, was, and is, the scarcity of water, even to drink. The placers lie about 700 feet above the head of the Arizava river, which winds its course six or seven leagues away to the north and east.

From the town of San Francisco, built right among the placers of Los Llanos, and due west some four leagues, was soon discovered the placera of La Cienega, grander in extent even than those of San Francisco.

Cienega proved a much more favored region from the fact that a great belt of limestone crossed the placers from southwest to northeast, and through which a subterranean water-course had cut its way, that required but tapping to come in abundance to the surface. At the southeastern edge of the placers the town of Cienega, with a beautiful oval reservoir in its center was soon built, the population reaching at one time 15,000.

However, in nearly all cases the placers were and are to-day worked by "dry-washing" processes, with bateas, haskets and blankets, and now mostly by dry-washing machines, the latter being something similar to the machines

used in many warehouses for cleaning grain.

The working of the sands at Los Llanos and Cienega was pursued industriously and successfully for many years, and is even the source of a considerable income to-day, to those who have capital enough to employ dry-washing machines. From the most authentic accounts and records kept in the State of Sonora, both official and private, the writer estimates that eighty millions of dollars have been taken from these two placers alone since their discovery.

On the writer's visit to these placers in 1872, and again in 1874, as one of the directors of an American company, formed in San Francisco for the complete exploiting and working of these gold-fields by American methods, I found the two little cities of San Francisco de Los Llanos and La Cienega a mass of almost undistinguishable ruins, with here and there a remnant of a once church tower or spire, with the walls of vast and commodious buildings at one time, crumbling to the ground; hardly a shelter left where we could camp with comfort or safety. Yet at this time there were under different managements, fully 50 of the dry-washing machines, spoken of above, with about 300 Mexicans and Yaqui Indians at work on different parts of the placers.

The dry washers were generally located on the higher ground, or on mounds made from previous workings, six men being allowed to each machine, one at the feed-hopper, two at the shaking and agitating oranks, one to manage, prospect and clean up, and two to carry up the dirt from the pits of caving, running sands, from a depth of about 15 feet. The coarser parts of the dirt are sifted by the machine from the finer, and run out over an upper shaking table, while the finer particles are dropped on a canvas apron, through which air is blown by a bellows below. A day's work of a machine from dark in the morning till dark in the evening, may be set down, at 30 tons, of 2000 lbs. with a result of about 20 cents per ton, unless in favorable ground, and the occasional finding of a "Chilepa." The wages of the Indians, is 60 cents per day each; they board themselves, the owners furnishing supplies, equal to one-half the wages at fully 75 per cent profit. The dry washers cost on the ground about \$70, and need but few repairs; the latter being easily accomplished by the use of what has not been ineptly termed, the iron and steel of Mexico—rawhide. In a future article I propose giving you the exploiting and experiences among these placers, assisted by the use of modern methods.

CHARLES MARION TYLER.

San Francisco, April 6, 1891.

A Peculiar Occurrence of Gold.

C. H. Aaron writes to the *Engineering and Mining Journal* as follows:

While in Honduras recently I found gold in what is to me a novel connection. I had heard of it before I saw it, and, whether unusual or not, it was a puzzle to prospectors and mining engineers alike.

The ore was a ferruginous quartz occurring in small veins near Concordia, in the Department of Olancha. When ground to pass a 40-mesh sieve and washed in a horn spoon, a white or yellow substance was found which was so little heavier than the iron oxide as to be separated from that only with difficulty and by a peculiar manipulation. No gold was seen, although the assay showed in some cases as much as four ounces per ton.

On grinding the substance in an agate mortar, gold became visible, and on treatment with nitric acid the white matter dissolved with effervescence, leaving yellow, flocculent matter and a considerable quantity of high-grade, clean gold.

These facts seemed to indicate calcium, strontium or barium as carbonate, but the nitric solution did not respond to tests for these nor for lead. I then felt almost sure that I had spathic iron to deal with, but on charcoal before the blowpipe the stuff melted, gave a yellow sublimate which was not that of zinc, and, on addition of sodium carbonate to the assay, I obtained a head of blismuth. The yellowish matter inclosing the gold was, therefore, blismuth carbonate stained by iron oxide.

I afterward dissolved a quantity of the substance precipitated by dilution, collected, and smelted out a good head of blismuth.

This reminds me of a characteristic reaction of blismuth which I have never seen mentioned outside of my own publications. If a head of pure blismuth is melted before the blowpipe on a cupel, and allowed to cool, it becomes covered by a film of brown oxide. This much everybody knows; but if the cooled head is examined it will be seen that the film of oxide is cracked across the top, and the bright metal is visible in the fracture.

In the case of blismuth, which I have smelted before the blowpipe from the native carbonate, the behavior was a little different; instead of the film being ruptured in the form of a crack, the head gave birth to a minute globe issuing from the side, to which the globe adhered, remaining lustrous, while the parent head was dull. These phenomena I have verified repeatedly, they are referable to the well-known expansion of blismuth at the moment of solidification after fusion.

CALIFORNIA COPPER.—There was shipped from here to New York last month 933,550 pounds of copper matte, 3900 pounds of ore and 72,000 pounds of cement copper.

The Molesworth Ore-Reduction Process.

About six months ago a new process for extracting gold from pyrites, or other refractory matrices, was invented by Mr. Francis Hylton Molesworth, of Adelaide, South Australia. Mr. Molesworth had previously filled the position of Lecturer on Analytical Chemistry at the School of Mines in Adelaide, and had for some time been carrying on experiments which resulted in what promises to become one of the most effective as well as cheapest processes yet discovered for nearly all kinds of refractory metallic ores. At first Mr. Molesworth directed his attention to the extraction of gold from pyrites, but as he continued his investigations and experiments, he found that the same process, with certain modifications was equally adapted to the extraction of other metals, as copper, zinc, antimony, etc. On the invention being introduced to the notice of a few practical business men, interested in mining pursuits, they agreed to form a syndicate to provide funds for erecting a large working model plant, and for securing patents for the invention in all the principal mining countries of the world. Several hundred pounds were expended in this way. The model plant was erected on the engineering works of Messrs. May Brothers, Gawler, and was found capable of treating about 30 hundredweight of pyrites per day. It was in operation at short intervals during several weeks, and the interest felt in it was shown by the numerous visitors, scientific, practical and speculative who went to see it at work. The directors of the New Alima and Victoria gold mine, where a considerable percentage of the gold is found in pyrites, were so satisfied with the success of the process that they entered into an arrangement with the Molesworth syndicate to erect on their mine a complete plant, capable of treating 100 tons of ore per week. Hitherto the process by which they separated the gold from the pyrites was almost entirely mechanical, but they found that the working model could do in three-quarters of an hour what their plan required 24 hours to accomplish. The plant was expected to have been at work nearly two months ago, but the strike at first caused some delay, and then a defective casting required to be reconstructed. Next, a little difficulty with the masons, and then the holidays have all helped to postpone the starting of the plant. It is only now waiting for the completion of a special chimney stack, which is very nearly finished, so that the opening is likely to take place very shortly.

The process consists in oxidizing the crushed ore or pyrites in a cylinder, which is kept slowly revolving in a furnace, where only a moderate degree of heat is required. The cylinder in the working model was five feet in length, one foot in diameter at one end, and nine inches at the other (approximately). Within the cylinder there were a number of small flanges for the purpose of carrying round the pulverized mineral, so that on reaching the top it would fall clear to the bottom; the use of this arrangement will be seen presently. The cylinder is placed at a slight incline to facilitate the passing of the ore from one end to the other. It is fed at the upper and larger end from a hopper which delivers the ore into a small pipe containing an archimedean screw, so as to keep up a regular stream of pulverized ore into the cylinder, the upper end of which is otherwise closed. In the center of the top of the furnace an iron retort is placed a few inches above the cylinder. The retort is charged with crude nitrate of soda moistened with acid, and a bent tube conveys the gas down into the lower open end of the revolving cylinder.

The gas is a compound of oxygen and nitrogen, containing an excess of the former, and its effect on the particles of heated ore as they fall from the top to the bottom of the cylinder is remarkable; from a dull red they immediately become at almost a white heat, and the sulphur in the ore is rapidly and effectually driven off. The effect can be seen by removing a brick in the end of the furnace opposite the open end of the cylinder. The action of the acid on the nitrate of soda produces not only the gas above mentioned, but also nitric and hydrochloric acid, as well as sulphuric from the sulphur contained in the pyrites. These by-products are derived from the gases generated, and which are collected in a chamber especially constructed for the purpose. The cylinder is not allowed to acquire a greater degree of heat than what is described as "dull red," and is made to revolve slowly, so that the ore occupies from 10 to 12 minutes in passing through it. At the lower end it falls out into a receptacle, and is found completely desulphurized, so that it is fit for immediate amalgamation. But Mr. Molesworth prefers treating it in a bath of aqua regia prepared from the acids before mentioned. The gold being thus dissolved, the liquor is filtered through charcoal, which retains the gold, and the charcoal being placed in a furnace, the gold is smelted and recovered. Mr. Molesworth claims that his process will save from 90 to 95 per cent of all the gold contained in pyrites, and estimates the cost of the operation at about 4s. per ton of crushed ore, this cost including interest on the value of the plant. The cost of a plant to treat 100 tons per week is estimated at between £300 and £400. Hitherto it has been difficult by most of the ordinary processes to save more than 60 per cent of the gold in pyrites, so that if Moles-

worth's patent will save 90 per cent, that will be 30 per cent more than the ordinary processes (putting the expensive one of chlorination out of the question). And not only is its advantage seen in saving 15 dwt. where only 10 dwt. were got before, but in the lower cost of the process, so that 1 dwt. of gold would cover the cost of saving 15 dwt., whereas 2 dwt., under old systems, would be required to recover 10 dwt. Among other advantages possessed by this process are: (1.) The saving in grinding the stone, as screens of 48 holes to the square inch are quite fine enough, the desulphurizing process effecting all that is necessary on that grade. (2.) In treating sulphide ores an excess of liquor is produced, and can be used for treating other stone containing "flour gold," which by this means can be readily saved. (3.) The entire removal of the sulphur is not necessary so long as the pyrites are decomposed. (4.) It is impossible for the ore to "slag," as it must come out perfectly oxidized.

In the course of the exhibitions given of the process, Mr. Molesworth treated very successfully auriferous antimony from the Mount Ophir mine in the Hillgrove district of New South Wales, leaving the gold free and bright. Sulphide copper ore, much mixed with iron, from the Mutuoro was also successfully operated upon, and zinc blende in combination with silver ore from Broken Hill. The treatment of the antimonial ores was especially admired, and all the experts who witnessed it were loud in their praise of the process. In the case of the copper ores, many pieces as large as hens' eggs were desulphurized in 12 minutes on passing through the cylinder, thus showing that it is only in the case of the precious metals that pulverization is necessary. Mr. G. W. Goyder, C. M. G., the Surveyor-General of South Australia, among other scientific gentlemen, witnessed the process, and expressed his pleasure and surprise at the wonderful effects produced by such apparently simple means. In common with others, he expressed the opinion that if the working of the Molesworth process on a large scale prove as effectual as when shown at Gawler, it will revolutionize gold mining in Australia, and make remunerative hundreds, perhaps thousands of claims, that cannot now be profitably worked. — *Australian Mining Standard.*

The New University.

Senator Stanford, in speaking to a reporter concerning the new University at Palo Alto, says:

"I have talked over the University matters with Prof. Jordan, and I expect him out here some time during April. In any event, he will be here by June. The University will be opened at least for the freshman class by October. Of course, in time, the University will be complete from the kindergarten to the post-graduate course, but that can only be after a village has grown up around the University."

"When the University opens there will be accommodation for about 700 pupils in the dormitories. My idea is not to build big dormitories, but to have 20 or 25 in each, thus making a sort of club."

"The technical department of the school I propose to have more complete. There is no use filling a lad with learning and then turning him out to earn his living when he does not know how. We will teach him, then, to use his hands. Any profession he chooses he can take up and learn there. By this course, I think we will turn out an improvement on the usual graduate from Eastern colleges."

"Young fellows—nice, bright and well-taught boys—come to me continually with letters from friends, asking for positions for them, and yet there is nothing they can do. They have to begin, then, right at the bottom and learn how to work."

"The girls will be accorded the same privileges as the boys, as far as their sex will permit."

"The University will not be free. It has been decided that better results can be gained otherwise." There will, however, be provision made for all sorts of free scholarships, and everything possible will be done to help poor boys to get an education. The institution is designed mainly to benefit middle-class people, though the sons and daughters of the rich will be as welcome as the others."

"I have not decided on any other professors as yet. In selecting the remainder of the faculty I will be guided to a great extent by Prof. Jordan, who knows them all. He is a Cornell man, and the Cornell course more nearly coincides with my ideas than that of any other of the colleges."

NEW IMMIGRATION LAWS.—The amendment made by the last Congress to the immigration law, and relative to the importation of aliens under contract or agreement to perform labor, was put into effect on April 1st. The amendment creates the office of Superintendent of Immigration, who is to be appointed by the President, with a salary of \$4000 per annum. The new law makes it an offense for any teamship or transportation company to invite or encourage the immigration of any alien through agents, either by writing or printing, or by oral solicitation, except by ordinary commercial letters or advertisements, merely giving the sailing date of vessels and terms and facilities of transportation. The amendment makes it an offense to encourage any alien to migrate to this

country on the strength of any printed advertisements or circulars holding out offers of employment. All aliens coming on such representations will be treated as contract laborers. This does not apply to State Immigration Bureau's offers.

Mica in Australia.

The *Australian Mining Standard* says: Although the mica discoveries in the northern portion of South Australia have been mentioned in previous issues, the subject is of sufficient importance for further notice. Since the previous references, additional information shows more clearly than before the value of this mineral. It seems highly probable that the mica mines will become a source of national wealth, the size and quality of the deposits at the MacDonnell Ranges being exceptional. Every one who has viewed the sheets of mica lately brought down to Adelaide by the discoverer, Mr. Benstead, is unanimous in praising their extraordinary size and quality. Within the last eight or ten years the demand for mica has largely increased, and the price has risen fully 200 per cent. The uses to which mica is applied have also increased in proportion, and a large demand for the article for electrical purposes has sprung up. The large sheets are especially adapted for the armatures of dynamos and condensers for electric lighting, for which purpose, being a non-conductor, it is well adapted and so commands a high price. We have quite recently heard from a professional expert that it is used in the Bank of England as a practically indestructible medium on which to write, with a sharp-pointed style, important records. The writing, which is scratched into the substance of the mica, is afterward smoked over the flame of a candle, and the smoked surface being rubbed clean, the writing alone remains the black. The same expert, Mr. Heinrich Keuper, states that he has traveled through the great mica mining districts of Russia, but nowhere has he seen any samples to equal the material which he was shown in Adelaide. It may be allowable to repeat the dimensions of the sheets exhibited. The smallest pieces were 3x4 inches, and others of various sizes beyond, some being 8x10, 8x12, 10x14, 12x14, and 18x24 inches. The following quotations are copied from a recent price list received from America: 1½x2 inches, 40 cents per pound; 2x4½ inches, \$1.10 per pound; 2½x7½ inches, \$3 per pound; 3x6 inches, \$7.50 per pound; 8x9 inches, \$9.75 per pound; and larger sizes, \$10 and over. The mica from the northern mines can be obtained six times the largest size given in the above list, so that it should fetch a proportionately higher price. These quotations, high as they are, have received confirmation from an independent source, a letter having been received from London by one of the partners of a large commercial house in Adelaide, the writer of which mentions an interview he had with a dealer in London who offered him 32s. per pound for moderately large sheets, but said if he could bring him a sheet 18x24 inches he could give him £20 for it. One sheet measuring 40x44 inches was got out at the mine, but being thought too large for carriage was cut in two. Further discoveries in the same district have been reported, and great interest is felt in the development of this important industry. Mr. Dyke is expected to arrive in Adelaide shortly with over a ton of good mica. The vast importance of these discoveries from a commercial point of view can hardly be overstated. We have here indicated a few of the uses to which mica can be put. These do not represent one-half its utility. It is such discoveries which stamp Australia as one of the most remarkable mining countries on the face of the globe, and prove that its resources are illimitable. South Australia is to be congratulated that its vast northern regions, though denied rain and pasture, have been supplied by bountiful Nature with products which will contribute greatly to the national wealth.

THE GRIPPE IN NEVADA.—W. S. Morgan, a mining man from Carson, Nev., who is stopping at the Commercial hotel, is authority for the statement that the men employed at the Holmes mine at Candelaria, Nev., have suffered terribly from the ravages of the grippé. "Out of 600 men employed in and about the mine," said Mr. Morgan yesterday, "more than 400 have been prostrated and something more than 100 have died. The disease raged for a time with such violence that work in the mine had to be practically abandoned and the company's physician was himself prostrated from overwork. There has been an abatement of the disease within the last few days, I understand, but a great many of the men are still unable to work. This is probably the worst case on record, and proportionately knocks the death-rate in Chicago from the same cause into a cooked-hat."

CONTRACTS have been let for the construction of 14 miles of the track of the San Francisco and San Mateo railway, an electric road to run from this city to the Baden stockyards. California material will be used exclusively. The rails are being turned out as rapidly as possible at the Pacific Rolling Mills, and it is proposed to spare no expense in the construction of the line.

JOHN KELLY, superintendent of the Bodie Cons. Mine, was shot by James Grant at Bodie last week. The wounds are serious but not dangerous.

Mining in Lower California.

Consul Viesoa of La Paz, writing to the State Department, describes the condition of Lower California as very backward. He says, although the republic of Mexico has enjoyed of late years an uninterrupted period of peace and prosperity, it is a noticeable fact that this peninsula has not been in the ranks with other parts of the country in its development and advancement during this epoch. Much no doubt is due to its topographical situation and to the great want of facilities for periodical communication with other parts, for as yet there are no telegraphs or cables existing, and it has happened at times that an entire month has elapsed without receiving news from the balance of the world.

Under such trying circumstances it is difficult for any country to make any progress. It is quite true that its agricultural resources are very limited, but there are other elements, such as mines, pearl fisheries, dyes of various kinds, etc., which offer inducements to enterprising people. The present settlers are, as a rule, little inclined to mining ventures, and, in fact, but few are acquainted with mining, which will undoubtedly later on constitute the wealth of this country. As it is, in this immense territory of 8709 square leagues there are but 21,000 inhabitants, of which perhaps about 1000 are foreigners.

It is gratifying to note, nevertheless, that what few industries exist are in a prosperous state. The following is a statement of the mines now in operation: The Bileo Company, situated at Santa Rosalia, about 200 miles from this port and about opposite the port of Guaymas, is controlled by parties in France. It has an immense plant of machinery for smelting great quantities of copper ore daily, and the group of mines which furnish the ores seem to be very extensive, and are connected with the works by railroad.

For a long time after the commencement of operations by this company it met with severe reverses and heavy losses caused by fires and floods principally, and partly through mismanagement, but withal, the mines proved themselves good, and the concern is now in a prosperous state. The company employs from 1000 to 1500 men constantly, and a town of considerable importance has suddenly sprung up in the vicinity. The shipping at this place has now become very important, and during the last fiscal year it appeared in the Government statistics of customs as the third port in the republic.

The fact is attributed in a great measure to the circumstance that every necessary article for the maintenance of the place, such as fuel, beef, produce of all kinds, materials for building, as well as all kinds of goods, have to be imported, as the country in that vicinity does not produce anything whatever. The landing place is an open roadstead, and at times it is dangerous to vessels lying at anchor. During September last two foreign ships were driven ashore in a squall and lost.

The Angeles Bay Gold and Silver Mining Company is also in a prosperous condition, and although now working on a small scale it is capable of being extended. The San Antonio mining district, in the southern part of the peninsula, is the location of the Progreso Mining Company, which is without doubt the most important in the territory. This company has in operation one of the most complete and perfect plants of machinery in the country, and its silver mines are in splendid condition. The ores are not, as a rule, of very high grade, but this is compensated for by the abundance of the yield. This company is in a flourishing state, and with the large force of men in its employment, it is a source of maintenance for the most part, of this district.

The San Antonio district is worthy of mention as a great silver mining country having a number of mines which might be worked to advantage. The Mexican Mining Company, a newly-formed company, is now working and prospecting some of these mines preparatory to introducing machinery. The results met with lately are very encouraging, and it is to be hoped that after all these facts become better known to the public, immigration and capital will be finally induced to this district. The shipments of bullion and ore from the above district to the United States during the last year were valued at \$606,280 in gold, while the imports of machinery, lumber and provisions from the same source amounted to \$133,108 41.

RAILROAD CROSSINGS.—In confirming the judgment of the lower court in New Jersey, in the case of a killing on a railroad crossing, the U. S. Supreme Court says: "While those using public highway are under the duty to keep out of the way of railroad cars crossing it, and to exercise such care as circumstances make necessary, the railroad company in moving cars upon its road is bound to exercise like care toward those who are obliged to pass over its tracks. The right of a railroad company to the use of its tracks for the movement of engines and cars is no greater in the eye of the law than the right of an individual to travel over the highway extending across such tracks."

The Southern Pacific Company will soon equip 20,000 freight cars with automatic couplings, to replace the old style of iron drawheads, with link and pin attachments.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

BELMONT.—*Ledger*, April 4: The superintendent reports the surface tunnel has been advanced 20 feet the last week, the face of the tunnel now being in solid ore highly sulphureted. The 10-stamp mill is running full time, and the yield in amalgam from the sluice plate is excellent.

PIONEER.—Mrs. Langhorst and Geo. Weller have sold their stock in the Pioneer M. Co., consisting of 46 shares. W. F. Detert was the purchaser, as the agent of other parties. It is expected, also, that Mrs. Walther's stock, consisting of about 20 shares, will change hands shortly. There are 320 shares in the company.

PIONEER CREEK.—Cor. Amador *Dispatch*, April 4: Pioneer Creek is getting to be quite an enterprising place once more as several quartz mines have started up lately and all seem to be producing ore at a lively rate. The most prominent among them is the Gracy mine. Some months ago, Mr. Gracy started a tunnel to be 500 feet in length to tap the Sunny South mine, some 40 or 50 feet deeper than the old works. When he had run in about 300 feet he struck a well-defined 3-foot ledge that prospects from \$50 to \$60 per ton. This has every indication of being a permanent and well-defined ledge, as he has sunk a shaft to water level, some 50 feet below the tunnel, and as evidence of its holding out he has about 300 tons of that valuable ore on the dump. The Griesbach Yelmini mine is about 6 or 8 feet in width and of low-grade ore, but there is no doubt, as they drive their tunnel ahead they will strike a richer rock, as this mine heretofore has produced ore of a pretty high grade. They have a new ten-stamp mill at the mouth of their tunnel and everything is in ship shape for work. The Bowman mine has out about 100 tons of \$20 or \$25 ore; the mine looks well but for some reason they are not working at present. We understand they are going to start up as soon as they can get their ore milled so as to make room for more ore. Mr. Kimball has also struck a ledge of about \$20 per ton ore, and has a shaft down about 60 feet deep and levels run 40 or 50 feet each way, the ledge being small. No one was surprised at Mr. K.'s striking a ledge as he has a mineral rod and consequently can find a ledge any time he chooses. Jack Porter has struck the extension of the Griesbach Yelmini mine; it prospects very well for top rock and we have no doubt but it will develop into a good paying mine.

Butte.

LARGE NUGGETS.—*Chico Chronicle-Record*, April 4: Yesterday a reporter of the *Chronicle-Record* learned that several valuable gold nuggets had been found on Rancho Chico by a hunter. Some time in the latter part of February a man by the name of McCabe, who resides near the residence of Mr. Meyhem in Chico Vecino, went hunting in Iron Canyon. Becoming wearied he sat down to rest and refresh himself on a side-hill. With his boot heel he uncovered a good-sized nugget of gold. Being unacquainted with the metal he was somewhat in doubt as to what it was, but its weight excited his suspicion. With a stick he probed the earth and succeeded in bringing to sight another, several times larger than the first. With the crude means at hand he could not uncover much ground, but several small colors were secured after the nuggets were picked up. He kept the secret some time until one day he made a confidant of Mr. Meyhem, as he recognized in him a man who would be likely to know the value of his nuggets, if they were gold. Mr. Meyhem took the nuggets to the Bank of Chico where he found that the largest one weighed 4 ozs. and 14 pennyweights. The place where the gold was found was then visited and when the men returned Mr. Meyhem interviewed Gen. Bidwell as to what arrangements could be made to develop the claim, as the property where it was situated belonged to him. After making a satisfactory agreement another visit was made to the place, this time in company with the General. We understand that Gen. Bidwell has agreed to work the claim and allow Mr. Meyhem and Mr. McCabe a certain part of the profits, if there are any. He reserves the right to stop at any time if he finds that the working of the mine affects Big Chico creek, near which the claim is situated. Col. C. C. Royce, business manager of Rancho Chico, who was one of the party to visit the spot, was seen last night. He expressed an opinion that the nuggets found were probably all that there was, and that there might be nothing left. To him the prospect of a big mine is not very promising, but nevertheless, of course, it is impossible to state for a certainty. The nuggets were shown us last evening and they were indeed beauties.

Nevada.

BRUNSWICK CON. MINE.—*Grass Valley Union*, April 4: Supt. Fitzgerald's last letter to the home office at New York says of the Brunswick mine: Continued improvement during the week has taken place in east drift, and a decided and very good improvement in the ledge, which has widened in size to 3½ feet and looks as if it would fill the whole drift. The ore is about the same kind as before, not so much sulphureted, but it is the same ribbon rock. If it holds out it is a fine milling proposition. It looks more like a mine than ever. I did not expect to find such a width of quartz so near the shaft. Shares to the number of 7500 were dealt in at the New York Mining Stock Board last week at prices ranging from 9 to 12½¢ per share.

WORKING BLACK SAND.—*Grass Valley Union*, April 3: Arrangements are being made for the shipment of a considerable quantity of black sand from the gravel mines at Dutch Flat to the new Extraction works at Grass Valley, which are now ready for business. This sand contains gold that could not be extracted by the ordinary sluice-working processes.

NORTH BANNER MINE.—*Grass Valley Union*, April 5: A station is being cut out for the 400 level of the North Banner mine. The lode in the mine is showing strong and is of high grade. Besides the footwall ledge, which is 3½ feet in width, there is another ledge coming in from above, also carrying good ore. The vein is making strong to the north of the shaft, and is also coming in good size to the south of the shaft, where heretofore it has been

small. The mine is now able to furnish more quartz than can be reduced by the company's 10-stamp mill. For the coming month the product of the mine promises to be larger than on any preceding month since operations have been carried on, and the continuance of monthly dividends may be expected.

MINING ELECTION.—The annual election of the stockholders of the North Banner Con. Tunnel Co. was held yesterday, at which the reports of the officers were received and accepted, after which an election was held of five directors to serve for the ensuing year. The following were chosen: George Fletcher, John F. Kidder, E. H. Brown, A. Materson and W. E. Brown of San Francisco. The Board organized by electing George Fletcher president and manager; John F. Kidder, vice-president; E. H. Brown, treasurer and Thos. J. Michell, secretary. The Board voted to pay a dividend of five cents per share, amounting to \$5000, on the 20th of the present month.

NORTH STAR DIVIDEND.—The North Star M. Co. has declared a dividend (No. 6) of 50 cents per share, payable on the 8th inst. This dividend will amount to \$50,000, making \$300,000 in all declared by the present company. There are other dividends in sight in the mine.

OMAHA MINE.—Friday was regular monthly payday at the Omaha mine. There are 150 men on the regular payroll, besides tributaries and contract men. The mine is looking well throughout and is producing largely.

MORE RICH GRAVEL.—*Transcript*, April 1: At the Harmony yesterday there was found in the north drift, at a distance of about 800 feet from the incline, gravel that pays on the bedrock \$5 a pan according to some of the workmen, but which is said by Foreman Helm, who is an extremely conservative man, to go "as high as \$2.50." From the present face of the tunnel to the old workings it is a distance of 175 feet north, and the bedrock is pitching in that direction. At a distance of about 650 feet north from the bottom of the incline, east and west drifts were run and made good developments. The main tunnel upon being extended from that point encountered a raise in the bedrock which led the management to recently raise up ten feet and continue ahead on top of it.

THE STEEP HOLLOW MINE.—*Transcript*, April 6: The company recently organized in S. F. to work the Steep Hollow quartz mine is building a stretch of road for a distance of nearly a mile to give better access to the property than is afforded by the old road which is frequently obstructed with snow in the winter. When this is completed and a boarding house is built sinking on the two pay shoots heretofore discovered will be begun.

THE GOLD BANK.—The G. V. Ry. & T. Co. are surveying from the mouth of their tunnel to the Oro Fino mine to obtain altitudes and depths and to get the "lay" of the shoots around the Oro Fino. When this is completed a test will be made of the gravel found in the drain tunnel and the driving of the main tunnel will be resumed.

HAVE FOUND THE LEDGE.—At Gooseberry Ravine this side of French Corral some boys recently found specimens of float quartz containing gold to the value of \$6, \$18, \$23 and \$32 respectively. Since then a party of men have been prospecting there and on Friday last they discovered a promising looking ledge which they will at once proceed to develop.

Placer.

NORTH FORK.—Cor. Greenwich *Bulletin*, April 1: The Dutch Hill mine is working a full crew of men. The company will soon begin running a new tunnel to tap the channel higher up. The Glazier Co. is still pushing ahead and taking out pay. The Sunnyside Co. continues prospecting with the view of tapping the main channel. Bressler & Davis will resume work on the Malvern Hill mine. Angus Cameron has completed his mine tank and is ready to begin washing gravel. H. Kelley is running a tunnel on Meaker Flat and taking out good pay. Sam Olsen is also taking out good pay above Bamboo Bar. Duryea & Savercoz are doing well at the Kirkham claim. B. Plazoni is running his tunnel. It is reported that his mine will be sold this spring to parties below. The "Nip and Tuck" mine is being worked by Pollard & Bamrick. Good pay is reported. Wm. Long, of Susanville, reports good pay in the tunnel of the Cariboo mine. Gardner & Trucks are working their mine at Cariboo successfully. Jeff. Buffington is working in his tunnel with good results. Several claims will be worked as soon as the water will permit. The outlook on the North Fork this season is good.

Plumas.

M. NOTES.—*National*, April 14: One day last week, the Pine Leaf Co., made some developments which promise to be something good. The company commenced prospecting some four years ago. After an unsuccessful attempt to reach bedrock with a shaft, a tunnel was run to tap the channel. The shaft was sunk to the depth of 89 feet, when the water became unmanageable, forcing them to abandon it. The company then devoted their time and energy in driving a tunnel, and after a couple of years hard work, succeeded in reaching the channel. The tunnel was run a distance of some 800 feet through hard bedrock, which made it slow and tedious, but the boys stayed with it, and it is hoped will be handsomely rewarded for their undertaking. The Tunnel is some 10 feet in bedrock. A raise was made in order to strike the shaft, when 2½ feet of fine gravel was struck, which prospected very big with the pan. On making the excavation for timbering the shaft, 5½ car-loads of gravel were taken out, netting \$2.12½ to the car. The indications are at present writing, that a fine body of gravel is ahead of them and there is no doubt that a good mine has been struck. The mine is situated at the head of Pine Leaf, two miles north of Spanish Ranch. The ravines and gulches paid big in early days, which is a favorable indication for a good channel. This locality bids fair to be the drifting center for Spanish Ranch and vicinity, as there are no less than seven companies pushing their tunnels in with all possible haste, hoping by spring to strike the channel. East of the Pine Leaf Co., are the Challens mine, the Iota mining Co., Murdock Bros. & Erickson, who are developing some three miles or more of the Challens channel. The Challens Co., have their tunnel in about 140 feet. They are working two shifts and pushing the work as rapidly as possible. The rock does not work to a good advantage, and does not blast well. The

Iota mining Co., have their tunnel in 150 feet and are driving it at the rate of 20 feet a week. They have good working rock, and hope to strike the channel by the first of April. The Murdock Bros. & Erickson are taking out gravel, which pays handsomely. On the west, Mat Kniewel is working away on the Summit channel and hopes, before long, to show the world good paying gravel. He is working on the north side of the ridge, tapping the channel by a tunnel. Abe Bolvar is bringing up his main tunnel and hopes by the first of March to be able to again take out pay dirt. Taking it all into consideration, there is no doubt, that by next summer, valuable developments will be made, and mining again receive a new life. As hydraulic is a thing of the past, the inhabitants are turning their attention to drifting, but as the channels are deep and long bedrock tunnels have to be run, it will take some time before anything permanent can be developed.

Sierra.

SUFFOLK TUNNEL.—*Mountain Messenger*, April 6: Rich pay gravel was found in the Suffolk tunnel at Wahoo, about the middle of last February, by David Moore, who is managing the property. This pay gravel was found near the line between the Suffolk and Golden Era, the latter claim lying north-east of the Suffolk, thus showing a continuation of the Western Union channel up the ridge toward Howland Flat, crossing on the way Golden Era, Pacific, Excelsior, California and other claims up the ridge. For this information we are indebted to Phil Doray, who is a large owner in the Era and Pacific. All the ground above the Suffolk can probably be worked through the tunnel; and if it should be that it could not, a short tunnel not over 2000 feet long can be easily put into the Golden Era ground.

EXTENSION.—Jeff Lawrence was here Thursday on a flying trip from Forest City and reported that the boys at the new Extension tunnel could see gold all through the gravel near the top of the prospect shaft, and small specimens had been picked up close to the bedrock. A working shaft, 100 feet ahead of the prospect shaft, is being raised to gravel, that may not be very far above the tunnel, as the red slate at the face, last Saturday, was so soft that breasting boards had to be used to protect the miners.

THE TELEGRAPH Co. has found good gravel in their claim at Fir Cap. How extensive the find is cannot yet be told, but there is a good chance for a very extensive drift gravel mine. Amos Hart and John Hainer are running a prospect tunnel below the old Badger Hill claims, on the South Fork. John Tournay has taken the interest of Frank Stewart in the claim which the latter was prospecting at the time of his death.

Siskiyou.

STARTED UP.—*Yreka Journal*, April 1: The mill at the Boyle mine on Humburg was started up about a week ago, with a large supply of quartz on hand, and a full force is at work getting out more. During most of last week, considerable snow fell on the summit of the Humburg range, making the old and new snow together, some four feet in depth, but affords good sleighing for hauling the quartz to the mill on sleds.

BLUE GRAVEL.—Lee, Lash & Co. still continue to realize good pay from the blue lead at Greenhorn, besides devoting much attention to ascertaining the course of the old channel and its extent. Louis Guilbert and Uley Brown who are now sinking a shaft in the Kildore hills, three miles south of Yreka, have struck blue gravel, and will continue sinking down until bed rock is reached, to ascertain how thick the strata is, and what it pays. Considerable stock has been taken in the Yreka Blue Gravel M. Co., and machinery will be secured as soon as possible for boring down to bed rock to discover at what depth blue gravel may be found in the vicinity of the Oberlin wagon road, where it crosses the divide from Yreka creek below the mouth of Greenhorn. M. McIntyre has lately discovered a very rich quartz ledge on Sucker creek, a tributary of Humburg creek, the quartz taken out showing considerable gold to the naked eye. It is believed to be a permanent ledge and of large size, at least such are the indications at the croppings. The quartz mill lately on Yreka Flats, is now being put up in the Long Gulch section, where Blessing & Co. and several other companies have a large quantity of quartz on hand to crush, and intend getting out more. There are several ledges on that gulch, and also at Loafer Hill, where Yreka Flats reaches Long Gulch. When the country south of Yreka is opened up extensively in developing blue gravel channels or leads, we may anticipate finding plenty of water that can be easily raised to the surface by pumps, for mining and irrigating purposes, with possibility of securing artesian wells in boring deep enough, to force the water up naturally. The miners in several sections of this county are unable to find any section corners for surveying their claims, as a large extent of the country mapped out has only been surveyed on paper. The Kildore Hills, south of town, and the country adjacent, is placarded with notices of claims taken up, since the discovery of rich blue gravel on bed rock at various places. The country, south of Yreka, on west side of Yreka creek, has never been considered as valuable for mining, but from present indications may turn out to be the richest mining section in Siskiyou. The gulches in the vicinity paid well in early days, but no one thought that rich gravel beds existed beneath the sand stone quarries and cement found at various points, on a line running directly through this section along the old Oregon wagon road to Siskiyou mountain via Butcher Hill and Willow Creek.

Tuolumne.

RICH STRIKE.—*Independent*, March 21: Great excitement prevailed last Tuesday in the neighborhood of Sugar Pine on account of a rich strike in Bernard Pacholke's mine, about three-quarters of a mile from the Green mine. Everyone for miles around came to view the golden discovery. Forty feet of the two-foot vein, carrying free gold the entire length, has been exposed. In almost every foot of the exposed vein gold is visible to the naked eye. From the rich nature of the surrounding country, and the unusual richness in sight, the Pacholke mine will undoubtedly prove to be a valuable one. We received a specimen of the ore, which is in free gold perceptible to the eye. The late strike is in the vicinity of the Green mine, also the Confidence and Excelsior, which properties have yielded millions of dollars, and from present indications more of the golden treasure will soon be extracted. The Green

mine has been incorporated and sold in shares in San Francisco, many shares having already been disposed of. An extension of the Green mine, owned and operated by J. T. Ryan, has a flattering prospect of future promise and prosperity.

STRIKE.—*Sonora Democrat*, April 4: A rich strike is reported to have been made in the Pirate mine, situated half a mile from the Excelsior hotel, at Sugar Pine. The mine is being worked by Bernard Pacholke and Frank Jasper. The richness of the ore has not yet been determined, but if Messrs. Pacholke & Jasper have any considerable quantity of ore similar to the specimen piece sent this office, Tuolumne may have a railroad yet. The Alameda mine, stated in last week's issue as the Chaparral, is not owned by a San Francisco party, but by M. B. Harriman, who has bonded it for 90 days to Irwin C. Stump, of San Francisco.

NEVADA

Washoe District.

CON. CAL. & VA.—*Virginia Chronicle*, April 4: There has been extracted from all parts of the mine 1540 tons of ore, which was shipped to the Eureka mill. Bullion shipped to the Carson mint, assay value about \$90,629.96. Bullion now on hand in our assay office, assay value, \$52,000.

OPHIR.—The west crosscut started from near the end of the drift run north from the drift run west from the winze, 122 feet below the sill floor of the 1300 level, has been extended 13 feet; total length, 25 feet, in a quartz formation showing low assay value.

UNION CON.—East crosscut No. 2 on the 1465 level, started from the north lateral drift at a point 200 feet south from the south boundary line of the mine, has been extended 23 feet; total length, 770 feet, continuing in a hard porphyry formation.

MEXICAN.—The east crosscut No. 1, started from the main north lateral drift at a point opposite the west crosscut No. 1, has been extended 19 feet; total length, 608 feet, in a softer porphyry formation.

YELLOW JACKET.—Shipping to the Vivian mill 38 tons of \$18 ore as per battery assays per day. Will commence to-day to ship about 90 tons of gold-bearing white rock daily to the Santiago mill.

CON. IMPERIAL.—We are still following up and taking out small streaks of ore from the upper levels and overhauling the old stopes.

CHALLENGE AND CONFIDENCE.—The joint Confidence and Challenge west crosscut from the north drift on the 300 level is out 46 feet, having been advanced to feet this week. The face shows quartz having no value.

SEG. BELCHER.—On the 600 level the east crosscut from the south lateral drift has been advanced 15 feet since last report, and is now out a total of 208 feet. The face is in porphyry and seams of clay. A portion of the week has been occupied in timbering the drift.

KENTUCK CON.—Raised one set in the east crosscut from the north drift, 1000 level; the top shows some bunches of ore, which were saved for pay. Started an east crosscut from the north lateral drift from the west raise, 1000 level, and advanced it 15 feet during the week; face in quartz of low-grade.

JUSTICE.—The north drift on the 822 level was advanced 19 feet since last report and is now out a total distance of 487 feet. The face is in a mixture of quartz and porphyry, which gives assays.

BELCHER.—No. 3 west crosscut, 300 level has been advanced 32 feet since last report; total distance, 249 feet. The face is in porphyry, clay and low-grade quartz. The east crosscut on the 1500 level is out 23 feet; the face is in porphyry.

ANDES.—The east crosscut from the south lateral drift on the 400 level has been advanced 18 feet; face in a formation of vein porphyry and clay. Easing timbers in main north drift, 420 level.

OCCIDENTAL.—The stopes on the 400 level are yielding some fair-grade ore. The south drift from No. 3 upraise, 40 feet below the 450 level, has been connected with the Nelson upraise; total length, 107 feet. The drift has been in fair-grade ore the entire distance, and is now in condition for stoping.

CROWN POINT.—The south drift on the 300 level is out a total distance of 75 feet having been advanced 25 feet during the week. The face is in clay and quartz with small bunches of ore. The 500 level west crosscut was advanced 18 feet since last report, making a total distance of 200 feet. The face is in clay and quartz.

SAVAGE.—We have hoisted 735 cars of ore from the 500, 750, 800 and 900 levels and from the intermediate below the 1300 level. Shipped to the Mexican mill 543½ tons and milled 550 tons; average battery \$15.42. We have bulled on hand and at the mill amounting to \$23,000.

HALE AND NORCROSS.—On the 1100 level of Norcross the north prospecting drift from the east crosscut has reached the north boundary, and is now being advanced in the Savage ground at the expense of the latter. On the 1400 level No. 4 west crosscut, near our north boundary was advanced 25 feet; total, 140 feet; face in low-grade quartz and porphyry.

SIERRA NEVADA.—West crosscut No. 1 on the 630 level from the northwest drift, 579 from the shaft, was advanced 40 feet; total distance, 265 feet. **UTAH.**—On the 725 level in the main west drift, at a point 140 feet from the shaft, a south drift has been extended 58 feet; total length, 114 feet, in a quartz formation varying from two to four feet in width, showing some value by assay.

POTOSI.—On the 930 level the east crosscut from the winze is out 240 feet; face in quartz, clay and porphyry. The winze is down 163 feet below the 1300 level; face in porphyry with streaks of quartz. The east crosscut from winze, 1300 level, is out from footwall 202 feet; face in porphyry and streaks of quartz.

CHOLLAR.—The south drift 1400 level was advanced 20 feet; total distance south of north line 30 feet; formation porphyry streaked with quartz. Joint east crosscut on the north line, 1400 level, is in 25 feet; face in porphyry. Milled the past week 519 tons of ore, worth \$20.49 per ton, as per battery samples.

EXCHEQUER.—East crosscut on the north line, 600 level, is out 161 feet; face in porphyry.

ALPHA.—The winze 80 feet north of shaft, 500 level, is down 73 feet; the bottom is in low-grade quartz. The north drift from the east crosscut, 180 feet east of shaft, 600 level, is out 69 feet, and connected with east crosscut 125 feet south of north line.

BEST & BELCHER.—Northeast drift from east

crosscut No. 1 has been extended 18 feet; total, 34 feet; face in hard porphyry.

GOULD & CURRY.—200 level: Have extracted from old stopes during the week the usual amount of ore.

Tuscarora District.

NAVAJO.—*Times-Review*, April 4: The 350 stopes are without material change, and are producing some very fine ore.

NEVADA QUEEN.—East crosscut from north drift on 650-foot level, has been advanced 30 feet in hard porphyry. Have started work in stopes above 550-foot level.

COMMONWEALTH.—Fourth level—West crosscut advanced 34 feet, still in porphyry. East crosscut extended 28 feet, water continues very strong. North drift from east crosscut extended 25 feet in the vein. South drift from same point advanced 30 feet.

BELLE ISLE.—The rich ore cut last week in the intermediate crosscut from No. 1 upraise, 350-foot level, continues. Drifts have been started each way on it, progress for the week 13 feet. Upraise to the east from the stopes, extended 4 feet and suspended. No. 2 chute is being extended so as to open up at that point the ore cut by the intermediate crosscut. The carload of ore sent to Selby's, sampled \$783 65 per ton.

NORTH BELLE ISLE.—North drift from Belle Isle 450-foot level extended 23 feet, the prospect continues encouraging. An upraise has been started 20 feet from the face, from which some high-grade ore has been taken, progress 11 feet. Sixteen cars of first class and 105 cars of second class ore have been taken from the 500 stopes. North intermediate drift from No. 4 chute, 600-foot level, has been extended 13 feet; the face is showing some very fine ore.

NORTH COMMONWEALTH.—First level—Has produced 20 cars first class ore average assay \$300 per ton, and 55 cars second class ore, assay from car sample \$18 per ton. Second level—North drift from west crosscut advanced 17 feet in low-grade ore, assaying from \$10 to \$35 per ton.

Pahrnagat District.

BONDED.—*Pioche Record*, April 2: S. T. Godbe, who has bonded three claims in Pahrnagat district, expects to begin development work on them some time next month.

Jackrabbit District.

DAY.—*Pioche Record*, April 2: The new air compressor at the Day mine is completed and was to have started yesterday afternoon to operate machine drills in the "December" strike. Air pipe is also being laid in the new tunnel and it is expected machine drills will be operating there in a few days more.

Pioche District.

Messrs. S. T. Godbe, A. Werner and William Lloyd, who own the Lincoln claim in the vicinity of the old Alps east of town, believe with others in the existence of a big vein in that locality and have just let a contract to sink the shaft 100 feet deeper. The indications are said to be good.

NEW FURNACES.—Telegraphic instructions were received last Saturday from New York by Supt. Godbe to at once begin the preliminary work necessary to the erection of two stacks at the new furnace site north of town. The first thing done will be the extension of the tramway to the new site, the laying of water pipes from town and grading. President W. S. Godbe of the company is expected from New York in about ten days with full plans and specifications for the new works, when we shall know exactly the program to be followed. Yesterday graders were put at work preparing for stacks and blacksmith shop, and a straight road, to be used for wagons and water pipes, is being cleared and graded from about the corner of Masonic cemetery to the new ground.

CLAFIN is the name given the new townsite, and like the name our town bears, it was first suggested by a lady, and is appropriate considering the fact that Mr. Clafin is the heaviest backer of the new enterprise, the successful operation of which means business prosperity for us and this section of country, better and more substantial than any we have enjoyed since what we are pleased to call "early days." This action of the mining companies in building is regarded as conclusive of the proposition of resuming work on the railroad, and that we have nothing to expect from that enterprise for an indefinite time.

ARIZONA.

RANDOLPH.—*Tombstone Prospector*, April 1: The Randolph mine changed hands to-day and will start up again under the management of Bausfield and Warner. The former was appointed agent of the company a short time ago and it is said the company will work it themselves. The work on the Mamie dumps is progressing with good results. The concentrates of the screenings with buddies is proving both economical and profitable. Dick Trezona and parties are chloriding the Bonanza near Last Chance and they are not dissatisfied. A whim is being erected on the claim being worked by Gage and Banning in the same quarter of the district. The lessees of the Junietta have been getting down to business with good prospects until yesterday when they had a falling out and work will not be resumed until Justice Alvord decides to-morrow for them who is right.

JEROME.—*Arizona Journal-Miner*, April 1: About 80 men are now employed at Jerome. Twenty men are also engaged in repairing the road and when completed freighting will be commenced again and the furnaces started up. Twenty men are also engaged in grading a sight for a new road. Six eight-horse teams are now engaged in hauling wood for the road and for the reverberatory furnace. Work will be carried on at this great copper camp during the coming summer on a larger scale than ever before, and within a short time it is expected that 200 men will be employed.

CATOCIN.—Supt. J. G. Marx, of the Catocin mine, has 12 men engaged in the development of that property. He says that the ore body is constantly increasing in width as depth is made. It is the intention of the owners to prospect it as thoroughly and as rapidly as possible, and should it hold out as at present, it will not be very long until they will erect a fine mill on the property to work the second-class ore. A carload of high-grade ore was received last night from the mine for shipment to a smelter for reduction, and another carload is already on the dump ready for shipment.

BRITISH COLUMBIA.

STRIKING OUT FOR THE HALL CREEK PLACERS. *Nelson Miner*, April 4: Long before the first day of June, the close of the lay-over season for alluvial claims, the owners of ground on Hall creek will have commenced operations. The representatives of 12 claims start for the creek next week. While they expect to find considerable snow on the ground, they go prepared to erect cabins and do other preparatory work that can be done as easily now as later in the spring.

CROSS-CUTTING THE SILVER KING ORE BODY.—The Silver King mine was visited this week by a number of local "experts," every one of whom say it is a wonderful property.

One "expert" in particular, whose mining experience was obtained while locating the Texas Steer, is enthusiastic at what he saw. He says the tunnel strikes the crosscut at right angles and within 3 feet of its west end, which goes to prove that the ore body is the full width of the crosscut—45 feet. The distance from where the ore body was first struck to the face of the tunnel is over 100 feet, with the face still in solid ore.

WORK CARRIED ON WITHOUT A MISHAP.—The working shaft on the Skyline, the Silver King of Hot Springs district, is down 190 feet, and a pump and station is now being put in, as water has been troublesome for some time. The shaft will be sunk another 100 feet.

A NICKEL CLAIM BONDED.—Whether or not the nickel claims in the vicinity of Nelson are workable propositions remains an open question. That the ore contains nickel is well known, and it is equally well known that the ground is favorably situated for working. One of the best known of these claims is the Maud A., owned by E. R. Atherton. This week a coast capitalist secured a working bond on it, and by its conditions he will be required to expend \$500 in development work by the 20th of July next. If the work proves satisfactory, \$1000 is to be paid on the 20th of September, \$1000 on January 1st, 1892, \$2500 on June 1st, 1892, and \$2500 on September 1st, 1892; \$7500 being the selling price of the claim.

PREPARING TO SHIP ORE FROM GOAT RIVER.—While more or less active preparations are being made to carry on or begin development work on claims in Hot Springs and Toad Mountain districts, the owners of prospects on Goat river are not idle. Jap King is now on the Alice ground, and as soon as the work can be carried on to advantage will begin building a wagon-road from that mine to the steamboat landing of the Kootenay, a distance of 6 miles. The Alice ledge at the depth of 100 feet is nearly 6 feet wide, the ore being a good grade galena.

THE BEST DEFINED LEDGE IN THE CAMP.—There are a number of ledges in Hot Springs district, and each ledge has its partisans. The partisans of the Little Donald ledge, claim it to be the best defined in the camp, and that its continuity has been proved the greatest distance.

DAKOTA.

RICHMOND.—*Deadwood Pioneer*, April 1: Work is steadily progressing at the Richmond mine at Galena, under the superintendency of Prof. Havens. Several drifts that have been abandoned for years have recently been opened up, and some good ore found in them. The main drift still continues in high-grade ore, and the condition of the mine is extremely promising.

LITTLE SQUAW CREEK.—Some specimens of the recent strike of silver ore on Little Squaw Creek were shown in the city yesterday. The character of the ore is white quartz, impregnated with small pieces of galena. The ore shown yesterday does not seem to be very valuable.

TO SHIP ORE VIA THE ELKHORN.—The pile of ore at the Golden Reward chlorination works is running pretty low, and not enough teams can be secured, with the present condition of the roads, to haul sufficient ore to keep the works supplied. An arrangement has been made with the Elkhorn, by which ore is to be shipped over the B. H. & Ft. P. to Piedmont, and then to be re-shipped over the Elkhorn to the chlorination plant. This will commence as soon as the Elkhorn can put in a side track, and 50 tons a day will be shipped. There is now only enough ore at the works to run four days, and the teams are only bringing 15 tons daily. If the Elkhorn does not get its side track in by the time the ore runs out, some arrangement will be made with the D. C., to haul the ore. In case no arrangement can be made, the works will have to shut down, until the roads get in better condition.

IDAHO.

SMOKY.—*Wood River Times*, April 1: Frank Oliver got in yesterday from Smoky, having come on snowshoes to Humphrey's, thence to Hailey by stage. He and his partner have some ore in the Carrie Leonard, and will make a few shipments at any rate, this summer. The Carrie is looking well. The lessees of the Pot-Wrestler also have some ore out and some in sight. The Sunday claim, in which P. M. Bruer is interested, shows some 200-ounce ore—a width of 15 or 18 inches of it. The Silver Star miners are all working in ore. At the King of the West there is a good deal of 400 and 500 ounce ore in sight, and regular shipments will be resumed as soon as the roads are open. Joe Reedy has been working all winter on an ore-claim in the Tyrannis. There is some ore in the Flagstaff. The contractors working in the Galore-Stormy have had a bad time of it all winter. The rock has been hard as chain-lightning, and the water squirts from the sides and face so that they have to keep flat rocks against the crevices through which it comes in order to be able to work at all. And even then they are no sooner at work than they are wet as drowned rats. This indicates the proximity of a strong, well-defined ledge; and, as a matter of fact, the contractors expect to cut it very shortly. As a whole, Mr. Oliver says that there is more ore in sight in Smoky and the outlook for the district is better than it has ever been since the first discovery of surface deposits there.

TUNNEL.—*Idaho World*, April 4: Mose Kemper came to Wednesday from the new El Dorado, the other side of the More creek summit. The tunnel running to tap Mose's ledge is in 128 feet. He thinks it is within 20 feet of the vein. Dunn has sunk a shaft 50 feet on his ledge and has taken out

about five tons of ore that will mill at least 400 ounces of silver per ton. The silver is mostly in the form of chlorides. Dunn is also pushing work on his tunnel to tap his ledge at the depth of 500 feet. This tunnel will be 500 feet in length. It is now in over 100 feet. Mose visited Baoner. He says the Wolverine mine, on the 500 level, is immensely rich and the ledge is 12 or 14 feet wide, all pay ore. The Wolverine is now turning out the richest ore ever taken out in Banner district, even surpassing the rich ore of the famous Banner. The Wolverine is a mammoth ledge, while the Banner vein is small.

MEXICO.

NO GOOD.—*Tombstone Prospector*, April 1: Jno. Kelso returned last night from the gold diggings in Sonora which have created such an excitement in this section. He went there to partly satisfy himself, and partly in the interest of friends who had confidence in his judgment. The report he brings back is anything but favorable. He remained four days in the vicinity of the diggings and prospected them thoroughly. He also observed what others were doing and states that no man is making more than \$5.50 per day. There are about 50 Americans and 100 Mexicans there, and all the white men who can are getting out. Old John Parr is there waiting for Billy Pump to get back. Mr. Kelso met the latter going down. Bedrock is near the surface and is a smooth hard granite. The extent of the ground is a half mile on each gulch. Many Americans down there sent word to friends up this way not to come down. Four men, who were the first Americans in there, have been rocking for a month and have not made a cent, and have quit in disgust. Mr. Kelso will not go back and he advises all his friends to stay away.

MONTANA.

AROUND BUTTE.—*Miner*, April 3: The week in the mining arena of Butte has been one of unusual activity, notwithstanding the fact that very little work has been done at the Anaconda Co.'s property on account of the difference that has arisen between that corporation and the Montana Union Railroad Co. regarding the hauling of ore from the mines to the smelters at Anaconda. Outside of the Anaconda all the smelters, mines and mills have been running full blast, turning out gold, silver and copper in bulk. At the Boston and Montana works a new O'Hara calcining furnace is being built, which is indicative of the anticipation of a season of unparalleled prosperity by the company. Several of the matting furnaces are also being overhauled and put in first-class condition. As to the company's mines, only development work is being done, the ore extracted in driving levels, making upraises, etc., being sufficient to keep both smelters in constant operation. Just think of it! That enough ore can be taken out in doing development work to keep in constant operation two smelters having a daily capacity of 450 tons. It seems like a colossal statement to make, yet it is nevertheless a fact. Of the producers owned by the company the Mountain View, situated at the very pinnacle of the hill, is the largest. It is developed by a 1000-foot shaft, from which crosscuts have been driven to the two veins at intervals of 100 feet. The shaft is sunk between the two veins, and from the points where the crosscuts encounter the ore bodies levels have been driven almost the full length of the claim, opening up immense masses of solid copper-silver ore which will be allowed to remain underground until the new smelter at Great Falls is completed. Raises, too, have been made from one level to another in various parts of the mine, making complete air circuits, so that the workmen will not be bothered with impure air. The entire work of developing this property has been done under the direction of Richard Dawe, the foreman, than whom there is no better miner in the camp. The Colusa mines at Meaderville, also the property of the Boston & Montana Co., are being put in condition to withstand any demand for ore that may be made upon them when the new smelter is in operation. The two combined now yield about 300 tons a day, a mere circumstance to what they can be made to produce. The company, however, realizes that it is of no use to extract the ore unless it can be smelted, and therefore prefers to allow it to remain in the depths for the present. The Colusas are both in charge of Cy Gilbert, a miner of experience, and when the new Lewisohn shaft is completed to a depth of 2000 feet will be capable of producing at least 2000 tons of ore per day for an indefinite period. As is well known by all mining men of the camp, the East and West Colusas are contiguous to each other and connected at a depth of 500 feet, although the shaft of the East claim is 300 feet deeper than that of the West claim. It is not worked below the 500, however, for the reason that the company is desirous of putting in good condition all the ground from the 500 to the surface before going deeper, and this it realizes it cannot very well do without purchasing heavier hoisting machinery. The new shaft, which is being sunk almost on the line between the two drains and which has already reached a depth of 500 feet and been connected with the lower workings of the properties, will be supplied with a hoisting plant that will enable the company to go right on through to the 1000 mark. The Colusas, the Mountain View and the Pennsylvania are great mines and will become greater in time.

SINKING.—Butte *Inter-Mountain*, April 4: Sinking has again actively commenced in some of the larger properties. Foremost among this number is the Moulton. This property has continuously run on the supply of ore above the 700-foot level for the past 12 years and the reserve having become exhausted, the company has commenced a lift of 200 feet during the past week. The Alice having encountered a number of rich shoots of ore and all dipping towards the Moulton ground left no chance for the Moulton but to sink, run their crosscuts and commence the taking out of rich milling ore. The shaft is being pushed in depth both night and day by an eight-hour shift. When completed to the 900 there will be no delay, but the leads will be cut and once more the large mill of this company will be found amply supplied with ore and the mine working both night and day. Among the others that have deemed it the proper time to further develop their properties in this way by continuing in depth are the Germania, Vulcan, Clear Grit and Mountain Con. Others will shortly follow the example, chief among the number being the Parrot, Lewis-

son shaft, Harris & Lloyd, the Monitor Co. in Park canyon and others. One source of consolation for the coming spring and summer is the abundance of water which will insure the continuance without interruption of every smelting plant in the camp unless it be from accident. The placer claims can also have a supply that will last almost the entire season and the output of both silver and gold promises to far exceed any former year if the mines are kept in active operation.

NEW MEXICO.

DEVELOPMENT WORK.—*Silver City Enterprise*, April 3: The El Paso smelter has raised the price on the treatment of copper ores. The Pacific people have enjoined Skillicorn & Snyder from selling or working ore from the disputed ground. Two additional vanners are being put in place at the Pacific mill. When the mill again starts up the fifteen stamps will be dropping. The Pinos Altos mills will soon commence to re-concentrate their tailings and expect to be able to make a marketable product from them. The Lone Monarch mine, of Lone Mountain, which has produced over \$80,000, is now offered for sale by Thomas W. Hinson, administrator of the estate of George W. Manley. The Anson S. Copper company has two cars of copper bars at the depot ready for shipment and will soon have another car ready for shipment. The smelter has been shut down temporarily, awaiting the arrival of a chemist. The present shipment is worth from \$10,000 to \$12,000. Work is progressing on the Flagler reduction works. Laizure & Grabe have the contract for furnishing the brick, and are now about to turn a kiln of 150,000. It is Mr. Waring's intention to have sampling works in connection, where miners can have their ores sampled and sold to any of the smelters of the country.

PINOS ALTOS.—*Silver City Enterprise* March 28: Bell & Stephens have a large pile of beautiful ore on the dump, enough to keep the mill running for a long time. They are still pushing development in the mine. As previously announced in this paper, it is the intention of this firm to have a gold brick of one ton weight on exhibition at the Columbian exhibition, and if the present ratio or output is kept up, they can secure their brick in a few months. They have shipped about 250 pounds of gold in bars this month, to say nothing of the output in concentrates, which is quite considerable. Such a display at the exposition will be a world beater, and will prove to outsiders that we can produce bullion. The *Enterprise* doubts if there is another mining camp in the Rocky mountains which is netting as much profit to the operators as Pinos Altos and yet there is very little talk about the camp. If the camp was located in Colorado or California the mining papers would be full of it, but poor old New Mexico, handicapped as she has been, will soon force recognition as one of the greatest mineral regions in the world. The output tells the tale of prosperity, and men of means will not be long in opening up our vast resources after they are once convinced that the metal is here.

UTAH.

DEMAND FOR ORES.—*Salt Lake Exchange Journal*, April 3: It seems that the duty imposed on foreign silver-lead ores has proved a blessing to the ore-producers of Utah, notwithstanding the assertion of some of the largest smelting corporations to the contrary. The great demand for Utah ores just now is traceable to the fact that the eastern smelters must have fluxing ores, and they have found out that Utah is just the place to get what they want. Hence the keen competition among ore-buyers and the activity in the mining camps where our big producers are located.

FISH SPRING DISTRICT.—Messrs. J. C. Parr and E. J. Watson came in from Fish Springs district, Deep Creek, the first of the week, bringing with them specimens of ore from their claim, the Galena, that has caused considerable excitement among mining men. One specimen, a 60-lb chunk, on exhibition at McLelland & Smith's liquor house on East First South, runs as high as 60 per cent lead and 800 ounces silver to the ton. Stewart made an assay of another sample yesterday that went 72.5 per cent lead and 307.2 ounces in silver. The ore was taken from a ledge three feet wide and only a few feet under the surface. The owners left for the claim this morning for the purpose of sending in a shipment of the ore. They are enthusiastic over the find.

GILSON IN WITH RICH ORE.—*Salt Lake Tribune*, April 5: S. H. Gilson is back from Dugway, and brought in 17,500 pounds of rich ore. This will be sampled to-morrow and the results are anxiously looked for. The mine is in condition for two men to take out and sack a carload of ore in five or six days, and the extent of this body of ore is not known, but is believed to be quite large.

THE ORE MOVEMENT. The past week the roads were so bad that little ore came in from the camps, except from such big shippers as load directly into cars. Of course the bad roads do not interfere with such producers as the Lead Co. at Bingham, the Eureka Hill and Bullion-Beck, Tintic, which load from their bins, but it stops nearly all the shipments from most of the other mines. While this condition cuts off the supply at the smelters from the smaller shippers, the larger ones keep up the bulk so that the smelters are fairly well supplied with ore. Park City was quiet in shipping because of the roads; the Brooklyn, Highland and South Galena sent in their usual quota from Bingham; the Lead mill is running full, but the smaller properties at Bingham are not shipping, while in Tintic the Eureka Hill and Bullion-Beck & Champion Cos. sent in a good quantity of ore. Stockton sent in but little ore during the week, but the miners there are getting in good shape for large production when the weather becomes settled and the roads good.

FURTHER INQUIRY FOR MINES.—One of our real estate men, who also handles mining property, is in receipt of several letters from parties in Philadelphia who are making inquiries about good mines to invest in, either by purchase or in buying shares of stock of good companies. This is an evidence that good work is being done in advertising the great mining industries of Utah, and the business being transacted in the Mining Exchange from day to day. Never before has there been so much interest in Utah mines by the people both East and West as now.

MECHANICAL PROGRESS

Mechanical Draughtsmen.

Thanks to the excellent results of having good trade and industrial schools, the number of skilled mechanical draughtsmen worthy of the name is on the increase. This is a branch of the trade that requires men of more than ordinary shillity, and one, too, resolving only a small share of the credit due it. Upon the draughtsman depends more of the value of a machine when it is finally completed than upon any other workman engaged upon it.

The designing of machinery partakes both of art and science. One writer very truly says: "The true beauty of form in engineering designs follows the same rules as those which render a picture or group of statuary pleasing to the eye, and the graceful forms of a well-designed machine impress the mind with a sense of beauty, of fitness and of power."

For a man to be a good draughtsman it is necessary, first of all, that he should have a thoroughly practical understanding and knowledge of mathematics, especially of geometry and arithmetic. This is essential, because it enters into every detail of practice, and upon the accuracy of this knowledge depends a great deal, not only in relation to his own part of the work, but the work of others who depend upon his drawings and figures.

It is also necessary that he should have a thoroughly practical knowledge of mechanics, so that he can design a machine, every part of which can be easily constructed, simple, durable and symmetrical in all its parts. The importance of this will be seen from the fact that the draughtsman must know to a certainty every operation which the machine must undergo in the process of manufacture, and all the conditions under which it will work when completed. Theory alone is not of any practical use in this. It requires an actual mechanical knowledge and experience.

It is necessary that the design should follow construction to a certain extent. The machine should be built up in the mind before it is attempted to place it upon paper for the instruction of the machinist. So far as possible every part should be studied, and its form, size and its relation to other parts be determined, and all these requirements demand a great amount of very close observation of the practical part of engineering, and a very thorough training in theoretical investigation, which makes it a trade of strict requirements, and calls for a man of more than average ability.—*Manufacturer's Gazette.*

CURIOUS FEATS OF STEEL.—The finest grades of razors are so delicate that even the famous Damascus sword blades cannot equal them in texture. It is not generally known that the grain of a Swedish razor is so sensitive that its general direction is changed after a short service. When you buy a fine razor the grain runs from the upper end of the outer point in a diagonal direction toward the handle. Constant strapping will twist the steel until the grain appears to be straight up and down. Subsequent use will drag the grain outward from the edge, so that after steady use for several months the fiber of the steel occupies a position exactly the reverse of that which it did on the day of purchase. The process also affects the temper of the blade, and when the grain sets from the lower outer point toward the back, you have a razor which cannot be kept in condition, even by the most conscientious barber. But here's another curious feat that will take place in the same tool. Leave the razor alone for a month or two, and when you take it up you will find that the grain has assumed its first position. The operation can be repeated until the steel is worn through to the hilt.

THE ARCHITECTURAL APPLICATION OF IRON AND STEEL.—Of course, the question will have to be considered not merely from a utilitarian, but also from an æsthetic point of view, and in approaching this less familiar ground, an engineer will naturally be unwilling to rush in where angels fear to tread; but there are perhaps a few common-sense principles which may safely be referred to. In the first place every architect is the horn enemy of shams, and if we are seeking to discover the true outlines of a style of iron construction, we must at once set aside every device for disguising the real nature of the material. Massing entablatures and cornices of hollow cast iron can only be regarded as hollow shams, and constitute an offense against good taste, which has been perpetuated often enough, and which reached its greatest extreme, perhaps, in certain buildings that were run up in America, where the entire Gothic facade, with its deep reveals, recessed and richly molded archways and supporting buttresses, were all done in cast iron about half an inch in thickness.—*Iron and Steel Trades Journal.*

ANCIENT LABOR UNIONS.—In the *Cosmopolitan* for March is an article on "Labor Unions in Ancient Rome," by Professor Leipziger, in which he shows the ancient origin of the organizations of workmen which afterward became the guilds of the Middle Ages and the unions of the present day. Corporations, or Collegia, as they were called, of seven trades, musicians, carpenters, goldsmiths, blacksmiths, shoemakers, potters, and a miscellaneous lot of trades all incorporated in one body, existed in

Rome way back in the times of the Kings; Numa is mentioned as their founder. The membership of these Collegia included independent, self-employing artisans as well as wage-workers, just as the guilds of the Middle Ages included the masters and the employees and apprentices. They grew rapidly in importance, and soon branches were formed all over Italy. In Rome they each had a building, in which their meetings and feasts were held. They had burial funds, such as our mutual benefit orders have, and their processions, festivals and anniversaries were frequent. They had full control of their own membership, and members had certain legal rights, such as the privilege of conducting their own law suits. Of course, their objects were mainly to keep up wages and the price of products, and give their members a monopoly of the market. To secure these objects they had to struggle with the non-union guilds and the unorganized labor, just as our unions do to-day, for they had no legal monopoly. Attempts to keep up the price of products led to several imperial edicts, which sought to prevent the corporations from successfully carrying out these "price conspiracies," as old Plautus styled them.

The first organized "strike" of which we have any record is mentioned by Livy as occurring in 312 B. C. It was a strike of the Roman musicians, who, on being deprived of the annual appropriation for their feast, left the city in a body, and refused to return until they received the appropriation. As their services were necessary for religious services, they won the strike without much difficulty.

The unions took an active part in politics, sometimes nominating their own candidates, sometimes endorsing others, and their influence was greatly respected and feared. A letter of the Emperor Trajan, in which he deprecates the political activity of the unions, reads very much like modern newspaper editorials of a certain class. The latter class prejudicially prevailed made the unions more desirous of showing their power politically, for socially a mechanic no matter how rich he might become, was a nonentity. A trader or merchant might buy his way into aristocratic circles, but not an artisan; he was looked on as but one degree above a slave.

PRODUCTION OF IRON.—The fact that the United States has doubled its production of iron since 1882, and is now the largest producer in the world, strange to say, excites little comment on the part of our English contemporaries. The *London Railway News* lets its home readers down easily by prefacing its statement on this head with the remark that, "As might have been predicted from the vast extent of its mineral deposits, the United States has attained," etc. The same journal also finds some comfort in the concluding statement that "the whole of the American production is consumed at home, and is, moreover, supplemented by the importation of a good deal of manufactured iron and steel in various forms." Fortunately, perhaps, for our contemporary, it has made no attempt to fix dimensions to this "good deal," nor to contrast it with the importations from England of a few years ago. Individually, we have no wish to see the United States prosper at the expense of a nation so near akin to us as England; but when American production exceeds home consumption as it must in the natural course of present events we may hear more vigorous comments and suggestions from our neighbors across the sea.—*Engineering News.*

THE USE OF ALUMINUM IN IRON FOUNDRIES. Mr. David Spence in the *American Machinist*, says: During the past winter I have used aluminum in foundry practice and find that it is a splendid thing to make iron fluid and clean. It seems to take all the impurities out of the iron when it is charged in the cupola with the pig iron. Ten pounds of Cowles' ferro-aluminum to 2000 pounds of pig iron will produce good, sound castings, free from blow holes. It is as good in the use of crucible steel as in iron (its effects). It produces a sharp and solid casting, makes a uniform grain. It takes away tendency to chill in cast iron. In steel it reduces the shrinkage and increases the welding properties in both wrought iron and steel. I recommend it to persons making tool castings, such as face plates, and in fact all kinds of work that has to be planed, milled or turned. There is one thing that I like in its use, and that is, it does not weaken the iron or take its strength from it, but rather adds to it. We are having good success with it in sewing machine castings.

OUR EXPORTS OF AGRICULTURAL IMPLEMENTS.—An official report from Montevideo announces that the United States is far ahead of any other country in the supply of agricultural implements and machines in Uruguay. These include plows, plowshares, mowing machines and axes, to which an English journal, the *European Trade Mail* remarks: "Reaping and mowing machines are obtained almost exclusively from North America, while Great Britain holds the market with respect to threshing machines. We are also first as regards spades."

OREGON'S GREATEST FOREST.—It is said there is a tract of forest trees in Southern Oregon embracing about 16,000 square miles, which, out and sold at \$10 per 1000 feet, would pay our National debt twice over. It is estimated that the amount of merchantable timber standing will reach 400,000,000,000 feet.

SCIENTIFIC PROGRESS.

A Study of the Axis.

During the last few years direct observations for latitude, repeated at a given station, have indicated a change of latitude; or, in other words, a change in the direction of the earth's axis. Other observations bearing upon the problem have been examined at the older fixed observatories, but the deductions are not accordant. Last year the matter was brought before the International Geodetic Association, and at the meeting of the Permanent Commission at Freiburg the results of a systematic series of latitude observations made at the observatories of Berlin, Potsdam and Prague were presented in tabular and graphic forms to the members and invited geodists. These observations indicated a change of the direction of the earth's axis almost identical at the three stations. In the discussion which ensued the results at other observatories were introduced to show different values and thus to indicate some other than a common cause. Nevertheless, a consensus of opinion was adopted, asking the co-operation of other observatories to further test the question. Prof. Mendenhall, Superintendent of the United States Coast and Geodetic Survey, was invited to co-operate, and several of the officers of that corps will take part in the systematic and simultaneous series of observations that will include work in the northern and southern hemispheres. On this, the Pacific coast, Dr. Marone, representing the International Geodetic Association, will reach San Francisco about the middle of the month and fix his station upon one of the islands of the South Pacific. On behalf of the Coast and Geodetic Survey, Mr. Preston will arrive about the same time and establish a station in the Sandwich Islands, where he has already made many latitude and gravity determinations for the Hawaiian Government. At San Francisco, the necessary observations will be made by Prof. Davidson of the Coast and Geodetic Survey.

The series of observations will extend through many months and will be made upon every available night at these and all other stations.

Several suggestions have been made to account for the observed changes in the latitude, such as the change in the refraction; slow but irregular hydraulic changes in the surface of the earth at given localities; slow but irregular changes in the level of the surface of the earth from the effects of solar heat; the irregular accumulation of ice caps at the poles of the earth, etc.

With skilled observers in Europe and in the Atlantic States, we must expect that some definite results will be obtained, either as pointing more directly to the cause of the apparent irregular movement of the axis of the earth or as indicating more definitely the necessity and character of further observations.

The Sap of Trees.

A keen observer and ingenious experimenter has been writing a book on "Sap: Does it Rise from the Roots?" a question which he proceeds to answer with a decided negative. To those who merely "run and read" the whole question and answer may appear as a very light matter indeed. In reality, however, the right answer to the question is of great moment to us all. In the first place, a negative reply simply means the ruthless uprooting of all our preconceived ideas, the reversal of what has been taught in our schools for ages. It is true that, if we examine into the theory of plant growth as set down by botanical and biological authorities, we find that they disagree among each other to an astonishing degree. They all, however, join in declaring that trees and plants derive sap from their roots and breathe in gases by their leaves. How the sap rises, whether by capillary attraction, endosmosis, root pressure, suction, or evaporation, or a combination of all (described by Professor Huxley as pulling, pushing, and dumping), the greatest biologists, including Herbert Spencer, Sachs, Huxley, Darwin, and others, have by no means been able to prove. They all, nevertheless, endorse the theory of rising sap, and agree, moreover, that it rises in spring and descends in summer. Now, if all this theorizing is proved to be wrong, we shall not only have to alter our school teaching, but largely modify our agricultural practice. Clearly, if the roots suck up, absorb, or otherwise collect moisture and the organic and inorganic constituents of sap from the soil, then the soil will quickly become exhausted and require constant feeding, while the leafy parts of the plants must be cut and pruned down. This is the present practice. And it is certainly worthy of remark that our best cultivated—according to the theories of the day—orchards and gardens are those that suffer most readily from blight and disease generally. Our new botanical revolutionist, Mr. J. A. Reeves, with his book on "Sap" tries to prove that we are altogether on the wrong road; that sap does not ascend, but descends, and that gas does not descend, but ascends in all trees and other plants. To the unprejudiced physiologist and mechanician this theory of Mr. Reeves seems by far the most credible and intelligible.—*Exchange.*

EARTHQUAKE PHENOMENA.—In the Ninth Annual report of the Geological Survey of the

United States, Captain Dotson presents an able and exhaustive discussion of the famous Charleston earthquake of August 31, 1886, the results of which are of much value. The earthquake is remarkable as one of great severity, taking place independently of any region of volcanic activity. The conditions existing for obtaining a full record, over the country involved, of the time, duration and effects of the earthquake, were on the whole unusually favorable, and some 4000 reports from 1600 localities were collected by the Geological Survey. The chief scientific result from the study of the earthquake is the conclusion as to the speed of propagation of the earthquake wave, the result being 236 meters per second. This velocity is not only entitled to much greater weight than results obtained in connection with similar phenomena elsewhere, but, further, it agrees closely with the calculated rate of propagation of a wave in an elastic, nearly homogeneous, solid medium of materials corresponding to those here involved. There were found to be two epicentral regions near Charleston, one 15 miles northwest, near Woodstock, about which the isoseismals are nearly circular, the other to the south of this and 12 miles west of Charleston, on Rantowles Creek, with oval isoseismals, the major axis extending toward Woodstock. At the former center the deduced depth of the focus is 12 miles, with a probable error of two miles; at the other the material for conclusion was less satisfactory, but the depth is made about eight miles.

CORAL GROWTHS ON SUBMARINE CABLES.—Very little is as yet known as to the rate of growth of corals, but some very interesting details have been published by Prof. Alexander Agassiz in the *Bulletin* of the Museum of Comparative Zoology at Harvard University, with regard to a series of specimens which were taken in June, 1888, off the Havana and Key West cable, from a portion repaired in the summer of 1881. Consequently the growth could not have been more than those of about seven years. It must be noted that this portion of the cable was laid at a depth of only from six to seven fathoms, and that the district in which it was laid was most favorably situated as regards food supply to the corals. Some of the apertures belonged to species whose rates of growth had never before been recorded. Verill mentions that the thickness of the *Orbicella annularis* coral formed in 64 years was not more than about 8 inches; the specimens from the Havana cable grew to a thickness of 2½ inches in about seven years. *Manicina areolata* has grown to a thickness of 1 inch; while *Isophylla dipacea* shows a still more rapid growth, projecting 2½ inches above the cable. Of course it is quite possible that these corals are of less than seven years' growth, but it is not probable that more than a short time passed before some of the swarms of pelagic coral embryos which must have floated past the cable found a place of attachment thereon.

VARIATIONS OF LATITUDES.—Experiments recently made in Germany have added convincing evidence to a fact already noted, to wit, the variability of terrestrial latitudes; for example, the latitudes of Berlin, Potsdam and Prague diminished between August, 1889, and February, 1890, about half a second of arc. In the latter year, between April and August, the latitude of Berlin increased four-tenths of a second. In other words, Berlin is nearer the North Pole in summer than in winter. The periodicity of these variations would indicate that the direction of the earth's axis, under the influence of some external or internal disturbance, was changing. This phenomenon is attracting very considerable attention.

PREPARATION OF GLASS FOR OPTICAL PURPOSES.—A new method for the preparation of glass for optical purposes has been devised in Sweden, and, according to *Revista di Artiglieria e Genio*, has met with marked success. The main improvement is said to consist in adding to the composition of the glass certain quantities of phosphorus and chlorine, which impart to it an absolute transparency, great hardness, and susceptibility of the finest polish. For achromatic lenses and fine optical instruments this glass is far superior to any make hitherto known, and it is said that the power of microscopic lenses can be greatly increased by this process.

THE RESPIRATION OF INSECTS has been the subject of study by M. Contejean, who has found that, contrary to what takes place in vertebrates, the movement of inspiration is passive and that of expiration active. The air is driven from the body by a contractile effort. Hence, when the insect is wounded, the flow of blood occurs at each expiration. The respiratory movement is not interrupted by cutting off the head, nor by the absorption of cyanide, which produces an immediate cessation in man.

SPIDERS differ from insects in five minute particulars: Their eyes are simple instead of compound; they have eight legs instead of six; they do not pass through the metamorphoses which are characteristic of insects; they have no antennae, and their breathing is accomplished by means of organs which combine the functions of lungs and gills instead of by tubes pervading their bodies.

THE ORGANS OF SMELL in the turkey vulture and carrion crow are so delicate that they can scent their food for a distance of 40 miles.

ELECTRICITY.

The Electric Railway.

We condense the following from a correspondent of the *Manufacturers' Gazette*: Great progress has been made in street transportation in all the great cities of the United States within the past few years, and nearly every town of any size throughout the country is realizing the necessity of providing some means of rapid transportation to its residents. A street railway system is likened to a number of great arteries carrying passengers to and from the heart, of the business center. Few people realize the immense business which is done by these railway companies.

There are at present five common methods of street transit: Elevated steam roads, steam dummies, horse-cars, cable-cars and electric roads.

To the first four there are many objections, which it is believed are obviated by the introduction of electricity.

An extra electric-power-house can be maintained at much less expense than can a large stable of horses, and both of these are necessary in an emergency.

In improving the present means of street-car propulsion by electricity, there is undoubtedly a great field open to the inventor, and such improvement would benefit the masses quite as much as anything else.

The electrician's part of the work has been well done, but the wear and tear on the mechanical parts of the system must be obviated by some means.

It is exceedingly difficult to answer as to the question of durability, as the cars have not been long enough in use. By use of the electric cars in Boston, the average speed of street cars has been increased from six to eight miles per hour.

A brief description of an electric railway as usually constructed is as follows: A power-house contains dynamos, which generate the electricity. This current is carried through a wire strung over the rails, thence down the trolley pole on the car to the motor, causing the motor armature to revolve; thence is passed through the gears connected with the car axle, and from the car-wheel returns, via the track, to the power-house, thus completing the circuit. The car is reversed by reversing the direction of the current through the motor, and is stopped by breaking the circuit. About two years ago an attempt was made to run electric cars in Boston without the aid of an overhead wire; instead, a conduit was placed in the ground near the track, and the current was taken from this, but this did not work satisfactory, as the opening became clogged with foreign matter, and for other reasons. Inventors are now at work devising some means whereby the conduit can be closed.

The propulsion of cars by means of storage batteries has also been tried, and some lines are working now, but the power required of the batteries is much greater than they can yield for any length of time.

So it seems that at present the only feasible system of electric propulsion is by the overhead trolley system.

ELECTRICAL WONDER WORKING.—The popular idea of electricity is to look upon it as a myterious force, coming from nowhere in particular, doing very nearly what it pleases, and equally able to produce a spark and a general derangement of the universe. There is a tendency on the part of certain people to contemplate as an African does his gree-gree a wonderful and ineffable something that need only be invoked to produce almost any result that can be named. This spirit has, perhaps, bastened the march of electrical industries, but it is certainly unworthy to encourage it. The sooner people are brought to look upon electrical power as only one of the protean forms of energy, as subject to known laws, and quite transformable into other kinds of energy, the better for everybody concerned. To be sure, we do not know what electricity is; in fact, it is quite probable that it is not a separate entity at all, but on the other hand, we do not know what the force we call gravitation is. Yet the action of both under given conditions can be foretold with considerable accuracy, and perhaps we should not be able to do much more with them, if Nature should yield up her profound secrets and set the unquenchable curiosity of man at rest. Look at electrical energy as a force obedient to certain laws, known and unknown, able to accomplish much in skillful hands, but do not imagine it as ready to do all sorts of marvelous things without any particular method in its madness. Electrical education has done much to familiarize men with the correct ideas of the subject, and probably this distributive teaching plainly enough that there is still much missionary work to be done.—*Electrical World*, N. Y.

ELECTRICITY AS A MEASURE OF THOUGHT.—Mr. J. L. Bain says: It is well known to the medical profession that every mental effort causes a rush of blood to the brain, and that the amount of blood depends on the "intensity" of the thought; but rush of blood means a rise in temperature, and if we could measure this we would be able to determine, in a rough way, the "power" necessary for the generation of any thought or mental effort. I accomplish this object in the following manner: I have a

head gear of some light, high-conducting (heat) substance. In its middle or any other convenient position I fix a thermo-electric pile, and connect this, by means of flexible wires or otherwise, to a sensitive galvanometer. The extreme sensibility of the thermo-electric pile is well known, and therefore whatever rise in temperature takes place, consequent to the rush of blood, would be instantaneously indicated by the galvanometer. The utility of such an apparatus may not appear at first sight of great importance, but if we consider for an instant the facility or difficulty with which children at school learn their lessons, any doubts we may have entertained as to its practicability will be immediately dispelled. By such a contrivance we could ascertain the "brain power" of boys and girls, nay, even men, and thus be in a position to indicate in what direction their mental efforts ought to tend.

GOOD HEALTH.

ETHER DRINKING appears to be a new form of intemperance which is just now creating much excitement in Ireland. The *London Times* sets it down as the true source of most of Ireland's woes. That journal has given a very elaborate account of the new tippie, the very existence of which was almost unknown until quite recently. The drink is a very impure form of ether and the results are most deplorable in character. The use of this new intoxicant has as yet spread through only four or five counties, but its march is onward and it is thought that it will continue to spread until all Catholic Ireland is involved. Insanity is rapidly increasing where this drink is used, and the death rate among the children of the ether-drinkers is very large. In Drapertown, with a population of only 9500, it is said there are not less than 6200 drinkers. In five of the northeastern counties, including Tyrone and Derry, where there is a population of 350,000, there are said to be 46,000 confirmed drinkers.

THE NEW YORK PASTEUR INSTITUTE appears to be doing good work in the prevention and cure of hydrophobia. The institute commenced work in February, 1890, and according to the annual report recently instituted it had received 823 persons bitten by dogs or cats. Of these, 643 received wounds from animals which were not mad, consequently their stay was of brief duration. In 185 cases anti-hydrophobic treatment was applied, the fact of the animals inflicting the injuries having hydrophobia being either clinically evidenced or proven by inoculation in the laboratory, and in numerous cases by the death of other persons or animals bitten by the same dogs. No death occurred from hydrophobia among the patients inoculated. Indigents were treated free of charge. Only 51 patients were received from the State of New York. The balance were from 25 different States, one going from Arizona and one from Canada. The result of the treatment has been a most perfect success.

CONSUMPTION AND CANCER.—The use of the lymph cure for consumption in this city is now generally conceded to be a failure, and we understand that there is now no special call for treatment; and since the Koch cure for consumption has got the go-by, Cook's cure for cancer is beginning to attract increased attention among many of the more considerate of our medical fraternity. The success attending the treatment of several very pronounced cases now in hand is proving a most agreeable surprise to many deeply interested persons, among whom are several physicians. We are assured that this cure will soon be taken up and thoroughly investigated by persons whose report, when made, will be most unhesitatingly accepted as beyond dispute. That it will be feasible goes without saying.

CARE OF THE BRAIN.—The brain stands the most abuses of any organ in the body. Its best tonic and stimulant is success. The worst and most depressing thing to it is failure. The most injurious effects come by using stimulants in early life. Young people should never use liquors, tea or coffee. The latter two may not exactly do harm, but they are conducive of no good. They act mostly on the brain and injure its growth very materially. Abundance of sleep is necessary. Eight hours is not more than enough. Sleep is the time of relatively lowered expenditure and increased repair.

THE BLACKENED TEETH of the Malay and Siamese are not produced, as has been supposed heretofore, by coating them with a mixture of betel and lime, but by rubbing the teeth with a paste made from charred cocoanut kernels. This is carefully applied to the teeth again and again, until a black varnish hides the natural white.

HYDROPHOBIA LONG DORMANT.—A telegram from the town of Mexico, in Missouri, says that William Garner, who was bitten by a mad dog about 20 years ago, died on the 25th ultimo. He was so violent during his illness that four men had to be kept with him all the time. His sufferings were terrible.

LOSS OF BODILY MOISTURE.—We lose two pounds of water in 24 hours by perspiration, and the more we perspire the cooler we become. There are 27,000,000 pores on the surface of our bodies, which, if placed in line, would extend 28 miles in length.

ENGINEERING NOTES.

The Jet System of Propulsion.

We have heard but little of the jet system of propulsion since the trial trip of the "Evolution," which steamed some 25 miles down New York harbor in November last, but succeeded in making only about one-third of the speed which had been calculated upon. The experiment cost the projectors about \$100,000, but whether the idea has been given up, or whether further experiments are to be made, to seek for some means of displacing the ponderous screw shaft and propeller, which all acknowledge is but a clumsy affair at best, is not known.

Water-jet propulsion is no new idea. Over 100 years ago, Mr. Ramsey placed a 50-foot jet-bomb on the Potomac, which made about four miles an hour. Watt experimented in the same line, and many others have also made unsuccessful essays.

All admit that the system is a most desirable one if it can be made a practical success. Its advantages would be simply tremendous, and their importance beyond comprehension. About one-half of the cumbersome machinery of a steamboat would be dispensed with in a jet-propeller, while the other advantages attainable would be equally important. All that would be needed would be a boiler and the simplest form of a steam-pump. By means of its enormous pumping capacity, a leak, however large, could scarcely endanger the vessel. The pumps would readily meet any possible exigency in case of fire. By opening bow-jets on either side, any ship, however large, could be turned almost or quite within her length; while she could have the full force of her power instantly applied to stopping her headway, when required. The jet applied to war vessels would possess great advantages in manœvering, while with her sides properly protected, no possible harm could come to her means of propulsion. There would be no racing to the jet propeller, no fractured shafts, no broken propeller, no loss of crew. A successful propeller will crown its originator with both profit and honor.

In most jet-propeller experiments hitherto attempted, the endeavor has been to make use of a very large jet nozzle. In the Fleischer experiment, made in Germany in 1879, the jet nozzle was about 40 square inches in area, which, with 100-horse power, developed nine knots.

The Thengroft experiment on the Thames in 1882, with a nozzle 9 inches in diameter and 170-horse power, developed a speed of ten knots.

In the late experiment with the Evolution in New York harbor, her originator, Dr. Jackson, held that a larger jet was a great mistake. He accordingly went to the opposite extreme and provided his boat with a small jet of only three-quarters of an inch jet, but propelled with a pressure of 2500 pounds to the square inch, which gave a velocity of 609 feet per second. She was a much larger boat than either of the ones above referred to and driven by a Rolocots safety tube boiler of 1200 indicated power. The power needed on the trial trip was said to be about 250. The speed obtained was only ten miles an hour.

There is a remarkable uniformity in the speed attained by these several boats, especially where the great diversity in propelling power is concerned. The displacement of the several boats was as follows: 14½ tons, 21 tons and 100 tons.

These experiments can hardly be considered as exhaustive, in view of the wide difference in conditions, especially between the two European boats and the American. It is scarcely conceivable how any engineer could think of beating the best type of propeller boat with a three-fourths inch jet of water in a boat of 100 tons displacement. It is possible, however, that a gradual cooling down of the nozzle is from the European experiments, and a proper adjustment of displacement and power may reach the happy medium, which will lead to success in revolutionizing the marine propulsion of the world. Further trials in this direction would be looked for with much interest.

A WORLD'S RAILWAY.—America, argues ex-Governor William Gilpin of Colorado, is a fallow continent, capable of sustaining half a billion people in happiness and plenty. It is the mission of the United States to be the distributor of food to the hungry of both Europe and Asia, lying as it does, midway between them. The time is at hand when all the ships of the seas will not be sufficient to carry the articles of commerce around the world to the nations fast enough. Then will come necessity for more rapid transportation. The plan of this transportation has been the dream of Gov. Gilpin for 47 years, and he prophesied its construction at an early date from that time. He has made one more prophecy. It is that the next great project in the world's material development will be the building of what he calls the Comopolitan railway—a railroad which shall gridle the earth. The first link in the chain is the Transcontinental road of the United States. Starting from the western terminus of that, the Comopolitan road will extend northward through Alaska, skirting the base of the Rocky mountains, where are plateaus that will render the building easy. Then will come Behring's strait, 48 miles wide, with a large island at its very center. There are no loc-

bergs in the straits, and it is shallow water all the way across with hard bottom and no engineering difficulties. Once across, the road would connect with the Russian railway through Siberia, connecting again with western and southern roads through Asia, Europe and Africa, and the work would be done.

USEFUL INFORMATION.

COMMERCIAL DRUMMERS OF ENGLISH ORIGIN.—An American who visited England more than half a century ago, when the commercial drummer hardly had an existence in this country, writes of this class of people in England as follows: "The commercial traveler is generally a young and very shrewd individual, possessing great savvy of manner and a remarkable ability to suit himself readily to all the varied moods of his varied customers. Furnished by his principals with choice samples of their goods, he steps into his chaise, or the stage, and with a light heart commences his circuit. At each town upon his route he tarries at the principal inn, where he is sure to find a hearty welcome. After thus ensconcing himself in comfortable quarters, he arranges his samples, and if it be forenoon puts them under his arm and issues forth to visit the storekeepers. Wherever he goes he is met with cordiality. Like all travelers, he is full of anecdote, and has at his command the rarest news of the time. None are more glad to see him than the storekeepers' wives and daughters. To these he imparts the most recent scandal and the latest fashions, affording them subjects for gossip until his next visit to the town. To the tradesman he lauds his samples with all the eloquence and ingenuity of which he is capable, and seldom leaves without making considerable bargains."

THE ANT'S JAW.—The grip of an ant's jaw is retained even after the body has been bitten off and nothing but the head remains. This knowledge is possessed by a certain tribe of Indians in Brazil, who put the ants to a very peculiar use. When an Indian gets a gash cut in his hand, instead of having his hand sewed together, as is done in this country, he procures five or six large black ants, and, holding their heads near the gash, they bring their jaws together in biting the flesh, thus bringing the two sides of the gash together. The Indians pinch off the bodies of the ants, and leave their heads clinging to the gash, which is held together until the gash is perfectly healed.—*Medical Record*.

SHOOTING LOGS.—The feat of shooting logs over the Snoqualmie falls, 60 miles east of Seattle, has long been talked of among the loggers. It is well known that above that cataract stand many millions of feet of fine timber, some of the best known in the State. This is inaccessible except by the means proposed, and hence the project thought of. The falls are over 400 feet high and at certain times of the year the flow is quite reduced. During freshets, however, there is an immense volume of water there, and then would be the safest time to float the logs down over. Several loggers, the most enthusiastic, claim they have tried the experiment and found it to work well.

GOLD IN DENTISTRY.—The French scientist, Victor Mennier, asserts that the American dentists insert in American teeth, each year, the enormous amount of about 1800 pounds of precious metal, which represents nearly \$450,000. This gold is buried with the person in whose mouth it is placed. Making allowance for the rapid increase in the population of the United States, and for the continued deterioration of American teeth, it would appear that in less than 100 years the American cemeteries will contain a larger amount of gold than now exists in France.—*Mining World*.

THE DAY OF OPPORTUNITIES.—This is an age for practical and thoughtful men in every line of trade and profession, or there is encouragement for those who are ambitious and energetic. There was never a time in the world's history when the opportunities were so great and openings more numerous for the attainment of position and influence. For the workingman, there is every opportunity to rise, to become a skilled and competent artisan, to excel in his line of work.—*Ez*.

THE GREATEST RAILROAD POTENTATE.—It seems a fabulous statement, but parties who claim to be posted make the statement that Jay Gould controls about 40 per cent of the railway mileage of the world. He does not, of course, actually own that amount, but has his plans so laid that the roads are under his control. This is power with a vengeance.

BOOTS WITH STONE SOLES.—A German inventor proposes to make boots with stone soles. He mixes with a water-proof glue a suitable quantity of clean quartz sand, which is spread on the thin leather sole employed as a foundation. These quartz soles are said to be very flexible and almost indestructible, while they enable the wearer to walk safely over slippery roads.

A WET silk handkerchief tied, without folding, over the face is a security against suffocation from smoke. It permits free breathing, and at the same time excludes the smoke from the lungs.

Passing Events.

The blue-grass region of Siskiyou county is being pretty well prospected just now, and seems to be more extensive than was at first supposed. A number of companies and individuals are at work and borings are being made. The prospects of the county as a mining field are encouraging.

Several people who went over into the Pah-rump valley region, where the alleged lost Breyfoyle mine had been found, have returned with the information that its merits have been exaggerated. There are numerous ledges, but of too low a grade for profit in such an isolated place.

The celebration of the 100th anniversary of the establishment of the American patent system began at Washington on Wednesday, in accordance with the program published in the PRESS.

Announcement is made of new gold fields in China and diamond fields in British Guiana, both so distant as to attract little attention here.

Two very important mining decisions were rendered this week, and are published in another column. One in effect lets the miners alone in the odd sections claimed by the railroad in Montana; and the other definitely settles the question of mineral claims on town-site entries.

It is estimated that \$50,000,000 are invested in the lumber business on this coast.

Mineral Lands and Town Sites.

The U. S. Supreme Court has at last made a direct decision on the subject of mineral lands on town site entries, after having several times passed upon it by inference and implication. The decision reverses the judgment of the Supreme Court of Montana. A. J. Davis held title to certain lands in Butte, under the town site entry act, one provision of which is that no title shall be acquired under the act, to any gold, silver or copper mines, or any valid mining claim held under existing laws.

Henry Wiebold, claims a title under existing mining laws, and when Davis offered to prove that at the time the patent of the Butte town site was issued the premises in dispute were not known to be valued for minerals of any kind, objection was taken on the ground that Wiebold's patent showed that as a matter of fact the premises did not contain valuable mineral land, and as such could not be granted by a town site patent. The Court sustained the objection, and this ruling, which was really decisive of the controversy, the U. S. Supreme Court now overrules.

The Court in the opinion, which is written by Justice Field, says: "The important question is whether, in the absence of knowledge that there were any valuable mineral lands within the town site, Davis can be deprived of premises purchased and occupied by him because of the subsequent discovery of minerals in them, and the issue of a patent to the discoverer. After much consideration we have come to the conclusion that this question must be answered in the negative. It is true that the language of the statutes touching acquisition of title to mineral lands within the limits of town sites is very broad, but in strictness they import only that the provisions of the town-site law shall not be the means of passing title also to valuable mining lands. We think they must be held merely to prohibit the passage of title to mining lands then known to exist, and not to prohibit the acquisition for all time of mines which then lay buried unknown in the depths of the earth.

"The object of the Town-site Act was to afford relief to inhabitants of cities and towns upon public lands by giving valid title thereto. Under such protection many towns, with buildings of great value, have grown up. It would in many instances be a great impediment to the progress of such towns if titles to those lands occupied by their inhabitants were subject to be overthrown by the subsequent discovery of mineral deposits under their surface. If their title would not protect them against the discovery of mines in them, neither would it protect them against invasion of their property for the purpose of exploring for mines. The temptation into such exploration would be according to the suspected extent of minerals, and being thus subject to indiscriminate invasion, the land would be to the one having the title poor and valueless, just in proportion to the supposed richness and abundance of its products.

"We do not think any such results were contemplated by the Act, or that any construction should be given to it that would lead to such results."

Mines on Odd Sections.

The U. S. Circuit Court at Helena, Montana, has rendered a very important decision in a contest between the Northern Pacific Railroad and Helena citizens on the subject of ownership of mines on the odd sections of land granted to the road. The decision is favorable to the miners, but the Court holds that the Northern Pacific grant is different from any other of the several railroad companies. The question at issue was defined by the Court as follows: "Whether or not a mining location made according to law upon an odd section of land within the limits of the Northern Pacific Railway Company's grant, and an application having been made by the locators thereof for a patent for such claim in the Land Office as mineral land, and claiming it to be such, and producing all necessary proofs of location, mineral character and work accompanying such application as is required by law and the rules of the Land Department, and which application is pending and a contest in regard to the right of the applicants to patent the same is existing in the United States Land Office at the time the railroad of the said company was definitely fixed, whether such mining location

is sufficient to take such land out of such grant, although admitted now to have been non-mineral in character and hence not subject to the Mineral Land act."

The Court holds that the filing of a general map of the route did not put into effect the withdrawal of the odd sections, but the lands granted were determined by the exact fixed route. Therefore, mineral claims or homesteads acquired prior to the designation of the route of the road were not void.

The decision of the Court is to the effect that the right of the Northern Pacific Railway Company did not attach to the odd sections until the line of definite location had been fixed and filed, as required by law, with the Commissioner of the General Land Office. The Court holds that there was a valid claim existing prior to, or at the time of, the definite location of the route of the road, and consequently the grant did not attach to the land in question. This decision validates a large number of claims of a similar nature to which contests had been filed by the railroad company, and which will now most likely be withdrawn.

Naval Designing.

The London Times, in speaking of our new navy, thinks that when the American iron-clads carry a full coal supply, their speed will be largely reduced. It says also: "If the greater boldness of the American designers is really based upon sound judgment, we need not regret it. We shall equally profit in the long run by their experience, whether it results in failure or success. We may, therefore, watch with keen sympathy workers on the same problem."

The question of design of vessels is a highly important one. Our international yachting contests have, in recent years, brought to the front both professional and amateur designers of no mean ability, and we have proven our nautical supremacy in this line at least. But in the branch of naval construction, one of the highest industrial importance, there are few opportunities for young men to acquire an education. The college and technical schools neglect this subject almost entirely.

As we are becoming a ship-building people on this coast, naval design and architecture should receive more attention here than is now the case. Senator Stanford, who is desirous of giving a practical education to the students of the university which he has established to the memory of his son, might do well to consider the desirability of including, among other things, the science of ship-building and design. Properly established and conducted, students in this line would come from all over the United States, for education in this direction.

The mathematical features of the science of navigation are taught now in the colleges, in a crude way, but he who is to follow the sea as an officer must attend a nautical school or obtain his experience on the deck of a ship. But in designing models of hulls, the study of form of ships and steamers, there is now no opportunity for a young man to perfect himself, except in the shipyard itself. Even there he is at a disadvantage, for the yard is distinct from the designing loft.

American ship designers of note have been very few as compared with the numbers of originators in other lines of industrial development. It is probably the case that opportunity to study the subject has been lacking. Senator Stanford has an opportunity to establish a new and valuable branch of study, the effects of which would soon make itself felt in one of our leading home industries. Our ship-building interests are sure to increase on this coast, and it will be well to prepare our young men with technical, scientific knowledge in that direction. Opportunity for experiment and practical illustrations in the direction of form of hull, power, marine engineering, etc., would be excellent at Palo Alto, with the bay near by, and large ship-building plants not many miles distant.

YELLOWSTONE PARK INCREASED.—By a proclamation issued by the President last Saturday there is added to the Yellowstone National Park a strip of land about 20 miles wide on the east side, and a wider strip on the south, extending over the great Rocky Mountain Divide, as far west as Idaho.

A CAVE occurred on Tuesday at one of the mines of the Detroit Copper Co., Clifton, A. T., but no one was hurt.

The Niagara Falls Power Plant.

Contracts for the drain tunnel for the great Niagara Falls power scheme have already been let by the Cataract Construction Co. of New York and the work is under way. This company, with a view of procuring the best possible technical advice as to the means of carrying out this work, invited plans from prominent engineering establishments in America and Europe. These plans were submitted to an International Commission composed of representative engineers from the United States, Great Britain, France, Germany, Switzerland, etc., with Sir Wm. Thompson as president. This board was convened in London and has been in session for the past month, having just concluded their labors and made their awards.

The Pelton Water Wheel Company of San Francisco was among those invited to submit plans, which embraced provision for a 120,000 horse-power plant in blocks of 20,000 horse-power each, and included the various systems of transmission of power called for, to wit: electric, hydraulic and pneumatic, it being the purpose of the company, after supplying local wants, to transmit a large part of the power developed to Buffalo.

Information has just been received that the plans submitted by the Pelton Company of this city have been favorably considered by the Commission and awarded the premium. They were the only plans from the United States relating to power development that had any recognition. This undoubtedly insures the adoption of the Pelton wheel for the greatest water-power plant in the world.

The wheel, as is well known, is an evolution of the old hurdy-gurdy wheel used so many years in the mines of California. The improvement, however, is based on scientific principles, which cause its remarkable efficiency, and have made it so markedly popular, not only in this country, but in South America, Australia, and other countries.

The invention of this simple water-wheel was not an accident. Its originator worked steadily for several years perfecting its details. He was at the time a resident at Nevada City, in this State, and had opportunity there for very elaborate tests on comparison with the turbines and other forms of water-wheel in general use. Very many forms and designs of buckets were tried under different conditions, and submitted to accurate and exhaustive comparative tests. Finally the form now so well known was adopted and it has given a degree of efficiency in every way satisfactory.

Now, coming into competition with all the water-wheels of this country and Europe, it is adopted as the motor in the largest water-power plant ever attempted, which is a sufficient evidence of its efficiency. Not only the inventor, but the manufacturers in this city are to be congratulated on this success. As much depends, moreover, on the manner in which the claims of a device of this kind are presented before an examining commission, praise is due to that skillful mechanic, John Richards of this city, who prepared the elaborate plans and specifications for the proposed plant. Inventor, manufacturer and designer are all residents of San Francisco.

THE CONS. VIRGINIA.—The Cons. Virginia and California Mining Co. is coming to the front again as a large bullion producer with dividends promised in the near future. In round numbers the bullion output for the month of February was \$133,000, and in last month it was \$172,000. The average battery assays in February was \$21.78 per ton, and in March, \$25.57. So far in this month they are higher than at any time in March. The company gained in March over and above all expenses, considerably over \$30,000. By the last of this month increased milling facilities will be secured, when the bullion output is expected to be increased correspondingly.

DESIGNS FOR COINS.—The Director of the Mint has issued a circular to artists for new designs for subsidiary coins. The general features of the present coins will be preserved to a considerable extent. The coins to be changed are the silver dollar, half dollar, quarter dollar and dime. These changes are to be made under the Act passed at the last session of Congress, which appropriated \$150,000 for the purpose, which sum is available on July 1st.

Coarse Ore Quicksilver Furnaces.

In a paper read some time since before the American Institute of Mining Engineers, Prof. S. B. Christy, of the University of California, described among others the continuous coarse ore furnace in use at the New Almaden mine, Santa Clara county, and which is illustrated herewith. They are coarse ore shaft roasting furnaces with exterior firelog. As will be seen from the horizontal sections and top view, the lower half of the furnace is a regular hexagon with shutments at the alternate sides. These shutments contain the fire, ash and draw-pits. Vertical section *AB* shows this still more clearly. Each shutment has on its face a fire-door and ash-pit door, which latter also commands the discharge-door for the spent ore. The spent ore, after being drawn from the cooling-pit of the shaft into the ash-pits, is left there until its fumes are exhausted, and is then drawn into the slag-cars through discharge-doors. These discharge-doors are placed on the side of each of the three shutments, lower down than the ash-pit doors. One of them is shown on the side of the shutment seen in the elevation.

The upper half of the furnace is cylindrical. It is closed at the top by a flat dome which contains the charging apparatus in the center. The fumes of the furnace are removed from the vapor chamber at top of the shaft above the surface of the ore, by means of iron pipes 12 inches in diameter. By means of short cast-iron pipes, these holes are connected with a cast-iron down-take by means of a rectangular system of pipes which encircles the head of the furnace. These pipes, inclined downward at an angle of 10°, lead into the condensers. To keep the pipes clear of soot, they contain small discs of iron. These discs are moved by iron rods, passing through stuffing-boxes at angles of the pipe system. They are only occasionally used, and the piston-rods are luted with clay when not in use.

The shaft itself is a cylinder, 6-foot interior diameter, by 11 feet 3 inches high, joined to the frustum of a cone 8 feet deep, contracting to a diameter of 4 feet at the bottom. Along the sides of the cylindrical part of the shaft, opposite each of the fire-places, are placed a series of four peep-holes. These, ordinarily closed gas-tight, are used to determine the height of the ore column and its temperature.

The fire-places and discharges have the details common to well-designed continuous shaft roasting furnaces of this type. The shaft and fire-places are lined with fire-brick; the rest of the furnace is of red brick, with the usual expansion space between.

The entire structure rests on a slightly cone-shaped iron plate which crowns the foundation. This causes any quicksilver that might permeate the masonry to flow to the center of the furnace bottom, where provision is made for receiving it. Experience shows, however, that this precaution is hardly necessary, as no metal has ever reached it.

The lower half of the furnace is inclosed by cast-iron plates, bolted and cemented with rust joints. The cylindrical part has a jacket of one-eighth inch sheet iron, and a cast-iron top plate crowns the whole, and makes the furnace vapor-tight.

The charging apparatus consists of a combination of devices used in iron smelting, viz.: the hanging cylinder and conical hopper. But, owing to the value and poisonous nature of quicksilver fumes, an additional cylinder and cover, with water or sand joint, is introduced above the other devices (section *AB*). The red moving the cone passes gas-tight through a stuffing-box in the center of the cover and is attached to a balance-weight. The cover itself is also attached to balance-weights by two chains passing over pulleys. The charging is thus easily effected without exposing the men to the fumes. The cover is lifted; a charge of ore and a little fuel is dumped from the ore-car into the hopper, and the cover is lowered into place. The charge is then allowed to warm in the hopper till it has nearly assumed the temperature of the top. This is done to avoid chilling the fumes and condensing them in the furnace by contact with cold ore. At the proper time, an equal volume of spent ore having been meanwhile drawn below into the ash-pits, the cone is lowered and the charge dropped into the furnace. The small quantity of fumes that

ASSAY FURNACE IN ISOMETRIC PROJECTION.

CONTINUOUS IRON-CLAD SHAFT FURNACE.

escapes into the space between the conical hopper and cover is allowed to cool a few minutes, and the cover is again lifted and a new charge is added to the hopper.

These furnaces were erected under the immediate supervision of Mr. H. J. Hattner. The details of construction are throughout excellent; they work admirably, and although they have been in almost continuous operation for nearly ten years, they have required hardly any repairs.

Assay Furnace.

In Leadville assaying is quite an important branch of the mining and smelting industries. In addition to the assayers attached to all the smelting and sampling works and to the principal mines, there are many independent assayers. Besides being employed as referees and experts in cases of dispute between mines and smelting works, the latter are patronized by prospectors and small miners. The chief assays made in the camp are silver, gold, iron and gangue assays, and at some smelters specific-gravity determinations of slags.

The laboratories are generally provided with permanent crucible and muffles furnaces, made of common brick, lined with fire-brick, and placed side by side, as shown in the cut, but very often the two furnaces are separate.

By means of the dampers *D'* and *D''* in the chimney, the assayer can regulate the draught and intensity of heat in the furnace. The apertures *A*, *B*, *C* and *D* are closed by means of sheet-iron plates, easily removed by tongs. Occasionally, portable clay furnaces of American or English manufacture are used for cupellation.

The Mining Companies' Financial Standing.

The following is the financial standing on the first Monday of the present month of the mining companies listed on the two exchanges in this city:

 (i) Due from other companies for pumping, \$12,800.
 (j) 5252 ounces unsold bullion (silver) on hand.

GOLD has been discovered at Ny Chow, province of Kwangsi, China, and many Chinese are going from other districts to the new fields. None of the California Chinese miners are reported as having started yet.

A New and Important Book on Metallic Alloys,
Solders, Etc.

RECENTLY PUBLISHED.

THE METALLIC ALLOYS

A Practical Guide for the Manufacture of all Kinds of Alloys, Amalgams and Solders used by Metal Workers, together with their Chemical and Physical Properties and their application in the Arts and the Industries; with an Appendix on the Coloring of Alloys. Translated and edited, chiefly from the German of A. Krupp and Andreas Wildberger, with extensive additions, by Wm. T. Brant, one of the editors of "The Techno-Chemical Receipt Book," etc. Illustrated by 16 engravings. 12mo, 428 pages. Price, \$2.50.

By mail, free of postage, to any address in the world.

A descriptive circular giving the full contents of the above book, together with a list of Important Books on Electro-Metallurgy, Moulding, Founding, Pattern Making, and Metal Working, sent free to any one who will apply.

Our new and revised Catalogue of Practical and Scientific Books, 87 pages, 8vo, and our other Catalogues, the whole covering every branch of Science applied to the Arts, sent free and free of postage to any one in any part of the world who will furnish us with his address.

HENRY CAREY BAIRD & CO.,
INDUSTRIAL PUBLISHERS, BOOKSELLERS & IMPORTERS,
810 Walnut St., Philadelphia, Pa., U. S. A.

A LIBRARY FOR \$1.00

Five books in one. Worth its weight in gold to every mechanic. The very latest information for 30 different trades. This wonderful book contains 575 pages absolutely teeming with rules, tables, secret processes, and new information that cannot be had elsewhere for less than \$25.00. The Model Steam Engine—How to Read an Indicator—The Westinghouse Air Brake—Blacksmith's and Machinist's Tools—Practical Mathematics Simplified—Tin and Sheet Iron Workers' Manual—Carpenter's Manual—Points for Painters—Magnetism and Electricity—How to Get a Patent—A Mechanical Dictionary. Everything fully explained in one handsome volume and guaranteed to be absolutely correct. Send \$1.00 for a copy bound in silk cloth, or \$1.50 for Morocco binding. With each copy of the book we give free a complete working chart for setting gear teeth. The regular price of this chart is \$1.50. **AGENTS WANTED.** Write for terms. **LAIRD & LEE, Publishers, 263 Wabash Ave., Chicago, Ill.**

Books on Working Ores.

By GUIDO KUSTEL, M. E.

ROASTING OF GOLD AND SILVER ORES (Second Edition) and the Extraction of their Respective Metals without Quicksilver. By GUIDO KUSTEL, M. E. 1880.

This rare book on the treatment of gold and silver ore without quicksilver is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe, and the why and wherefore. It contains 156 pages, embracing illustrations of furnaces, supplements and working apparatus. It is a work of great merit, by an author whose reputation is unsurpassed in his specialty. Price, \$5, coin, postage free. Sold by DEWEY & Co., Publishers, 220 Market St., San Francisco, Cal.

By C. H. AARON.

AARON'S LEACHING GOLD AND SILVER ORES, the most complete hand-book on the subject extant; 164 pages octavo. Illustrated by 12 lithographic engravings and four wood cuts. Fully indexed. Plainly written for practical men. In cloth, \$3. Sold by DEWEY & Co., S. F.

The Explorers' and Assayers' Companion.

A Third Edition of selected portions of the "Explorers', Miners', and Metallurgists' Companion."

A practical exposition of the various departments of Geology, Exploration, Mining, Engineering, Assaying, and Metallurgy.

Price, \$6.00 post-paid. Sold by DEWEY & Co., Publishers, 220 Market St., San Francisco.

By J. S. PHILLIPS, M. E.

The work is divided into four parts—Rocks, Veins, Testing and Assaying. The geological chapters are intended to give miners a practical idea of the various formations. The chapters on mineral veins are derived from long observation, and the section on exploration has been carefully considered. All that relates to discrimination and assay of minerals has been kept as free from formulae as possible. The work is written for practical men, and all the explanations and descriptions are clear and to the point. It is so prepared that it is useful to uneducated men as well as scientists.

California Inventors

MARKET REPORTS.

Local Markets.

SAN FRANCISCO, April 9, 1891.

Rains the past week insure good crops, while snow added to deposits on the mountain ranges give assurance of summer water for miners. With these favorable conditions, confidence is growing stronger, trade increasing and money becoming more plentiful. With our unusual large crop of wheat in this State and a higher range of values, the year ought to witness a degree of prosperity seldom if ever before enjoyed.

MEXICAN DOLLARS.—Continued dulness is the characterizing feature of the market. Nominally quoted at 78 to 78½ cts.

QUICKSILVER.—The market is more active. Low prices appear to induce buying. The price ranges lower than for several years. Receipts the past week aggregate 276 flasks.

SILVER.—Purchases by the Department are reported as follows in this month:

Date.	Offered ounces.	Purchased ounces.	Price paid per ounce.
April 3.....	915,000	370,000	\$ 98200 to \$ 98376
April 8.....	—	400,000	\$ 97990 to \$ 98000

Silver continues to hang around with a weak tone reported. To-day (Thursday) the New York market is easy and a shade lower. It would seem that with the Government buying 4,000,000 ounces of silver monthly that the surplus will be reduced soon to such small proportions as to bring about better prices. Possibly political trouble abroad may have a bearing on the silver market, which, if so, will with peaceful arbitration assured, react in favor of the metal. There can be no doubt but the large moneyed interests of the world are opposed to re-monetizing silver, for with it a commodity speculation to much better advantage in many articles of trade is assured.

LIME.—Receipts the past week aggregate 3546 bbls. The market is unchanged.

BORAX.—The market is reported unchanged. Free shipments eastward are still in order.

ANTIMONY.—While we are not able to obtain lower quotations, yet we are assured that purchases are being made slightly lower.

LEAD.—The demand for Alaska has been met. The market here is still unsettled. Our quotations are outside figures. Eastern advices are favorable to the holding interest.

TIN.—The market is reported steady, with canners using quite freely. Some parcels have been shipped to British Columbia. Alaska has taken quite freely. It is very generally conceded that an increased quantity will be used by fruit canners both in this State and Oregon.

COPPER.—The market is steadier. Our advices from the East and also from Europe indicate higher prices later on for outside stocks are being steadily depleted, and when they have gone into consumption consumers will have to secure their wants from holders who ask more money.

IRON.—Imports the past week aggregate 100 tons from New York. The coke strike at the East, foreign labor troubles with more trouble looked for in the United States after this month on the eight hour a day work, have their bearings on the market at the East and abroad and consequently an indirect bearing on our market. The consumption on this coast is not only larger than last year at this time but it appears to be enlarging, yet the stocks here and to arrive are enough to meet our requirements for some time to come. Quotations are nominal.

COAL.—Imports the past week aggregate as follows: Seattle, tons, 3190; Nanaimo, 4127; Departure Bay, 2500; Baltimore, 2600; New Castle, N. S. W. 1765. Total, 14,762 tons. The market continues in buyers' favor. It is claimed by some that a steadier feeling may obtain for spot steam in next month. Large consumers on the other hand say that the market is more apt to set off some more, than to steady itself. Temporary high wheat charters in Australia are against ships offering for this port, but after next month ships will be more numerous.

Eastern Metal Markets.

By Telegraph.

New York, April 9.—The following are the closing prices the past week:

	Silver in London.	Silver in New York.	Copper.	Lead.	Tin.
Thursday.....	44	93	13 75	4 55	20 35
Friday.....	44 11-16	93	13 75	4 56	20 40
Saturday.....	44	93	13 75	4 56	20 35
Sunday.....	44	93	13 75	4 56	20 30
Tuesday.....	44	93	13 76	4 56	20 30
Wednesday.....	44	93	13 76	4 56	20 30

Quicksilver is demoralized. Tin is steady. Lead in light stock with an increasing demand. Borax is easier. Copper is steadier with a firmer tone. In Philadelphia, the market for pig iron is as follows: Good irons are well taken up, but there is not the slightest disposition to buy for forward delivery, the impression being that the chances are in favor of lower rather than higher price, so, as the coke strike is settled.

The product of the Ontario mine for the first quarter of 1891 was \$146,667.19 from ore sales and 236,469.64 ounces of bitumen. The product of the Daily mine for the same time was \$30,449.55 from ore sales, and \$52,969.58 from sulphides.

List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific Coast.

FOR WEEK ENDING MARCH 31, 1891.

- 449,513.—FAUCET—M. Anthony, Berkeley, Cal.
 449,551.—ELECTRO-THERAPEUTIC SYRINGE—E. Bartsch, S. F.
 449,346.—KITCHEN CABINET—Brown & Smith, S. F.
 449,347.—HOOD FOR FIREPLACES—L. E. Clawson, S. F.
 449,208.—STEAM-ENGINE—E. W. Curtis, Portland, Or.
 449,210.—NEWSPAPER COVER—Jos. Davis, S. F.
 449,579.—SHADE ADJUSTER—H. Du Fresno, Portland, Or.
 449,316.—CARD SHUFFLER—E. Falkingham, S. F.
 449,322.—SECTIONAL ROPE SHEAVE—Harris & Thomas, S. F.
 449,445.—FEED MILL—Henry & Wood, Portland, Or.
 449,323.—CONSTRUCTION OF BUILDINGS—P. H. Jackson, S. F.
 449,221.—FARM GATE—L. J. Johnston, Petaluma, Cal.
 449,480.—ENVELOPE MOISTENER—E. E. Kingsley, Portland, Or.
 449,161.—HYDRANT—W. Lacy Jr., Los Angeles, Cal.
 449,292.—ORE CONCENTRATOR—F. B. Morse, Murphys, Cal.
 449,329.—GANG FLOW—J. & W. Patterson, Stockton, Cal.
 449,331.—FLOW—G. W. Phinney, Guerneville, Cal.
 449,338.—SELF-CLOSING GAS-BURNER—W. Ten Eyck, Oakland, Cal.

The following brief list by telegraph, for April 7, will appear more complete on receipt of mail devices:

California—Frank F. Eggers, San Francisco, electrical dental engine; John W. Gibson, San Francisco, dental engine; Albert Graff, San Francisco, piano; Constant Hartin, Willows, device for drawing steam beer; William C. McNeely, Sacramento, riding pad; Alexander Rudolph, San Francisco, window sash; William W. Slater, Oakland, automatic bellringer; William H. Thurman, Fish Camp, connection for wagon trains; Henry Tanker, San Diego, vehicle spring; Charles Vogel, San Francisco, three-rail track for cable railways; Charles Vogel, San Francisco, cable railway crossing; Charles Vogel, San Francisco, curve for cable railways; Henry W. Whitlow, San Francisco, breech-loading gun; Maude Wyman, Oakland, slate attachment; Oregon—J. B. Otto Boeslager, Mount Angel, propeller for vessels; William A. Campbell, Portland, saw guide; James Williams, Portland, rowlock for boats. Washington—Legrand D. Harding, Colfax, grinding mill; William B. Morris, Seattle, stump-puller.

Notes.—Copies of U. S. and Foreign patents furnished by Dewey & Co. in the shortest time possible (by mail for telegraphic order). American and Foreign patents obtained, and general patent business for Pacific Coast inventors transacted with perfect security, at reasonable rates, and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

CARD SHUFFLER.—Edwin Falkingham, S. F. No. 449,316. Dated March 31, 1891. This device for shuffling cards consists of a long narrow case or box having obstructing ribs placed across it at intervals, whereby a portion of the cards may be stopped, allowing those upon the top to slide over and be afterward followed by the others in such a manner as to intimately mix or shuffle them.

HOOD FOR FIREPLACES.—Leonard E. Clawson, S. F. No. 449,347. Dated March 31, 1891. This is a novel attachment which the inventor calls a "hood for fireplaces and grates." It consists of a hollow adjustable casing which is adapted to fit into the upper part of the grate opening. The use of this improves the draft of the chimney and causes the smoke to pass upward more directly, and any eddy or blast which is caused by the wind, and which would tend to throw the smoke outward into the room will cause it to follow the interior curves of the hood or front, and the smoke will thus be again directed into the chimney so as to pass upward and not be allowed to come out into the room.

PLOW.—Geo. W. Phinney, Guerneville, Sonoma Co. No. 449,331. Dated March 31, 1891. This improved construction of plows consists in providing the plow with a jointed beam, a means for turning the beam to one side or the other and maintaining a draft directly upon the point of the plow to whichever side it may be turned.

SECTIONAL ROPE-SHEAVE.—James W. Harris and Thos. J. Thomas, S. F. No. 449,322. Dated March 31, 1891. This invention is specially designed for use in the construction of large pulleys or sheaves of many feet in diameter having a peripheral groove around which wire or other rope is passed either for the purpose of changing its direction or of transmitting motion through the pulley. The rims of these sheaves wear out quite rapidly under the friction caused by the incessant rubbing of the steel wire ropes, which are used in cable railways and for other similar purposes, and in order to readily replace these rims or portions of them and to reduce the expense, these inventors construct the central portion of the wheel with its arms or spider separate from the rim, and the rim in several sections with a means for accurately fitting said sections together and securing them upon the ends of the arms of the wheel, so that when completed a perfect and evenly running wheel will be the result. Any rim-section may be removed, and another one introduced without throwing the rope off the wheel by simply turning the wheel so that the section to be removed lies on the inside and between the two parts of the rope which are tangent to the wheel-rim.

KITCHEN CABINET.—Millard F. Brown and Thos. E. Smith, S. F. No. 449,346. Dated March 31, 1891. The invention relates to a device to be used in kitchens which may be termed a kitchen cabinet. The invention is designed to provide a con-

veoient rotary adjustable cabinet with receptacles for various articles in common use in the kitchen and attachments for implements for the same purpose, and in connection therewith of an adjustable stand or table. The whole device forms an exceedingly convenient combination of receptacles and mechanical devices in one apparatus.

Mining Share Market.

Mining shares the past week gave unmistakable evidence how the few remaining outside dealers in stocks are at the mercy of manipulators. For three or four years, soon after Col. J. W. Mackay arrived from the East, the market went down and kept down until about the time he left for the Atlantic Coast. So accustomed is the public to this, when it was positively known that the Colonel was in this city a scare appeared to possess traders, and under this, selling prices gave way, causing a decline in three boards of from 15 to 25 per cent. Of course all stocks sold were absorbed by the two or three pools, which while seemingly operating against each other take good care to pull together. The decline which came the writer intimated when advising in last week's PRESS buying for cash. Everything now warrants the correctness of the writer's statement that a good profit will be made before 30 days by those who bought, even higher than the lowest prices that obtained last week. This opinion is grounded upon the general bear feeling among outside dealers, and where there is so much bear talk there is not much buying except by inside pools. The latter having large lines of stocks to sell and more assessments to levy and collect, must send prices up to draw in outside buyers. Con. Virginia's steadily increasing battery assays only help the bonanza stocks, and unless the entire line moves buyers are fearful. To move the line successfully more ore and higher assays must be made in other parts of the lode. It now looks as if Overman and Chollar will be made to do service in this direction, but if these two fail to draw in buyers at higher prices the other mines will come to the front. The great trouble now is that the Gold Hill and Middle mines are in poor repute. The prevailing opinion is that they have been, are being and will be looted for the benefit of a limited few, causing many to believe that to buy shares of those mines is to take to your breast a viper that kills financially. With such an odorous reputation it is hard for the managers to make very much of a deal. Assessments it is claimed by well informed parties will have to be levied right and left before 45 days pass.

Speaking of quite a general belief that the middle and gold Hill mines have been and are being looted, it is in place to state what came under the writer's observation regarding Yellow Jacket. In looking over files of the *Alta California* covering the Con. Virginia District in 1875-6 it was noticed that that paper as far back as then, openly charged that the Yellow Jacket mine was being looted. At a later date it appears that the Bonanza people secured control of the mine when dividends were in order. At the time they lost control, a dividend had been declared but under the new management it was rescinded, and it was not long thereafter before the reserve fund disappeared and an assessment levied, which was followed by other assessments. This was done too, while taking out and milling ore said to be of the same grade that the Bonanza firm had made the mine pay dividends. Hon. Francis G. Newlands' attention being called to the common talk that the mine was being looted instituted inquiries which resulted in higher battery assays. These assays nearly ever since Mr. Newlands went East, have been singularly uniform—\$18 a ton, which causes a large number of experienced miners to believe that there is something radically wrong, and as the gentleman is now or will be within a few days on this coast, it is not at all unlikely but his attention will be "drawn to the singularity of the assays—something never before known in mining.

The Con. Virginia Mining Co. boasts of possessing a Fish that knows all about what is being done in the mines. Owing to the value of this Fish the company has fitted up a fine office room. News from the Constocks report that Con. Imperial is shipping ore for milling. Overman is taking out higher grade ore, and consequently the weekly assays should show an increase. More ore is being milled by the company. Yellow Jacket is taking out ore which, if reports be correct, should mill over \$30 a ton in gold, but whether the company will return that or even \$20 a ton is by many a disputed

point. Crown point, Challenge and Confidence can take out, so it is said, good to rich ore whenever desired. Work in these mines and as for that several others may be of a delay character so as to freeze out outside stockholders. In the middle and north end mines, no ows is received different from that published last week, all still belong of a very encouraging character. If the public had confidence in the management of the mines on the lode, stocks would be selling at quite high figures. "The burnt child dreads the fire."

From outside mines the tenor of advices continue as heretofore reported. It looks as if the showing of ore from two of the districts will soon be of a more pronounced character.

THE PELTON WATER WHEEL

GIVES THE HIGHEST EFFICIENCY OF ANY WHEEL IN THE WORLD. OVER 1300 IN USE.

Affords the most simple and reliable power for all mining and manufacturing machinery. Adapted to heads running from 20 up to 2000 or more feet. From 20 to 30 per cent better results guaranteed than can be produced from any other wheel in the country.

ELECTRIC TRANSMISSION.

The advantages the Pelton Wheel affords in the way of a uniform and reliable power, close regulation, and the facility of adaptation to varying conditions of speed and pressure, have brought it into special prominence and extensive use for this class of work.

All applications should state amount and head of water, power required and for what purpose, with approximate length of pipe line. SEND FOR CATALOGUE.

THE PELTON WATER WHEEL CO.
121-123 MAIN STREET, SAN FRANCISCO, CAL., U. S. A.

PELTON WATER MOTORS. Varying from the fraction of 1 up to 15 and 20-horse power, unequaled for all light-running machinery. Warranted to develop a given amount of power with one-half the water required by any other. SEND FOR MOTOR CIRCULAR. Address as above.

THE GATES ORE AND ROCK BREAKER.

UNLIMITED IN CAPACITY, UNEQUALED IN EFFICIENCY, UPWARD OF 3000 NOW IN USE.

Will do more than twice the work of any other with the same cost in wear.

Gives a fineness of product that increases the capacity of any mill from 25 to 40 per cent without any additional expense. THE BEST AND ONLY CRUSHER ADAPTED TO MACADAM ROAD WORK. Send for Circular.

THE PELTON WATER WHEEL CO., 121-123 Main Street, San Francisco, General Western Agents.

NOTICE TO GOLD MINERS!
SILVER-PLATED AMALGAMATED PLATES
For SAVING GOLD!
IN QUARTZ, GRAVEL, OR PLACER MINES. MADE OF BEST SOFT LAKE SUPERIOR COPPER
AT REDUCED PRICES.

Our plates are guaranteed, and by actual experience are proved, the best in weight of Silver and durability. Old Mining Plates Replated, Bought, or Gold Separated. THOUSANDS OF ORDERS FILLED.

SAN FRANCISCO NOVELTY, GOLD, SILVER AND NICKEL PLATING WORKS,
68, 70 & 72 First St., San Francisco, Cal.
SEND FOR CIRCULARS.

JUSTINIAN CAIRE, Agent,
521 & 523 Market St., San Francisco.

—DEALER IN—

Assayers' and Mining Material.

—MANUFACTURER OF—

BATTERY SCREENS AND WIRE CLOTH

Agent for HOSKINS'

HYDRO-CARBON ASSAY FURNACES

IMPORTANT TO GOLD MINERS!
SILVER-PLATED AMALGAM PLATES for SAVING GOLD
In Quartz, Gravel and Placer Mining.

PRICES GREATLY REDUCED. ONLY REFINED SILVER AND BEST COPPER USED. OVER 3000 ORDERS FILLED. FIFTEEN MEDALS AWARDED. Old Mining Plates can be Replated. Old Plates Bought, or Gold Separated. These Plates can also be purchased of **JOHN TAYLOR & CO.,** Corner First and Mission Streets, San Francisco.

SAN FRANCISCO GOLD, SILVER AND NICKEL PLATING WORKS,

E. G. DENNISTON, Proprietor.

653 & 655 MISSION ST., SAN FRANCISCO, CAL.

Our Plates have been used for 20 years. They have proved the best. We adhere strictly to contract in weight of Silver and Copper. SEND FOR CIRCULAR.

RECEIVED EVERY MEDAL
Awarded on the Pacific Coast
for Silver-Plated Amalgam
Plates and Best Gold, Silver
and Nickel Plating.

IT HAS NO EQUAL.

The Late Governor Waterman.

By the death of ex-Governor R. W. Waterman, California loses one of her most prominent miners and foremost citizens. He came here with the early tide of the gold-seeking immigration and engaged in mining on the Feather river for two years. Returning East, he remained until 1873, when he again came to California to make his home in San Bernardino county. He immediately identified himself with the mining industry, in which he has since continued, making a large fortune by legitimate mining investment and development. With his partner, J. L. Porter, he took the leading part in opening the famous Calloo mines, the heaviest silver-producing district in California. It was here that he laid the foundation of his fortune, since accumulated not by "stock deals," but by honest mining work. Some years since, he purchased the Stonewall gold mine, on the Cuyamaca grant, San Diego county, a few miles from Julian. The mine had been abandoned some years, and by many was supposed to be worked out. Governor Waterman properly opened it, equipped it with a fine plant of machinery, and it was developed into a splendid paying mine. He told the writer, about two years ago, that it was paying him \$20,000 a month. He was naturally a large employer of labor, and invested his money in directions which developed the natural resources of the State. The portrait on this page is from a photograph made about two years since.

It is stated that Governor Waterman's fortune is about \$8,000,000, and not long since it was asserted that his increase from his mining property was \$1000 per day. He owned considerable ranch property in the Southern counties, and was interested in some local railroads as well.

The disease which caused his death was pneumonia, and it did its fatal work with irksome speed. He was hurried at San Diego with marked honors, on the afternoon of April 14th. Governor Waterman was a native of Herkimer county, N. Y., and a California pioneer. His chief field was mining and in it he

THE LATE ROBERT W. WATERMAN.

achieved great success and amassed a large fortune. He was elected Lieutenant Governor in 1886, and became Governor upon the death of Governor Bartlett in 1887. Probably no man ever labored harder to administer an office in accordance with his idea of right than did Gov-

ernor Waterman. He suffered from inexperience in public affairs, and made mistakes, but of his sincerity and uprightness there is no question. It is sad that after such an experience as he had in a high office, he was not given more time to enjoy the quiet of private life, of his fortune, and of the family ties which had such grateful influence upon him. He was but 65 years of age, and apparently rugged and good for many more years of earthly effort and attainment, but the summons came and was not to be deferred. His memory will be long cherished.

WHERE ARE THE TRUSTEES?—The Arnold Gold and Silver Mining Co. of Arizona was organized in this city in 1886, mainly with Eastern capital, and died a natural death in 1888, there not being any one where they had the mine. The company had a fine lot of machinery, having paid cash for the mill to the Union Iron Works, and bought the hoisting works on credit. When the company failed, the Georgine Mining Co. bought their hoisting outfit for \$25,000, but, strange to say, there was nobody left in the company to whom this money could be paid. A number of people have claimed it, but it must be paid to an officer or trustee of the original company, and none of these have been found. In two years the Georgine Co. have been unable to find the legal owners of the \$25,000, which is in the hands of Mr. J. Snutherland, now at the Palace hotel, in this city. The courts will probably settle the question of ownership.

DR. JORDAN, the newly elected President of the Leland Stanford Jr. University at Palo Alto, is now engaged in selecting the faculty. Leading specialists and men of high reputation will be secured from various American colleges and educators from across the ocean will be asked to fill the remaining vacancies.

REPORTS of mineral discoveries in South Dakota, and also the Cherokee Strip, are published, and some excitement prevails. The Cherokee Strip claims are gold quartz, and those in Hayward district, South Pennington Co., S. D., are silver-lead.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—Eds.

The Placers of Sonora, Mexico.

NUMBER II.

EDITORS PRESS:—Herewith please find two pen and ink sketches of the placers of Los Llanos and Cienega, the deposits of gold being indicated in a general way by dotted circles in the cuts shown on page 249. The originals were made on the ground by the writer in 1873; and may in a rough way, provided your space will permit publication, assist the general reader to a clearer estimate of the topography and size of the placers. From our survey, made with a view to obtaining a grant from the Federal Government of Mexico, we found that about 63 square miles would be required to cover the grounds of Los Llanos alone; and of this again, we estimated that some 30 square miles could be made available by the use of a complete hydraulic plant; such as can be seen in some parts of our own State to-day.

The natural fall of the ground of Los Llanos toward the valley of the Arltuavriver is fully two per cent over 100 feet to the mile, and in some parts much more. As there is little or no gravel to contend with, the dirt being finely disintegrated granite, slate, limestone, and quartz intermixed with a clayey loam, we anticipated but little difficulty in sweeping off the sands into the valley below, provided always that an ample supply of water could be obtained, and the use of various gulches as ground sluices, whose fall in some cases was much greater than have mentioned. Naturally, as is the custom of the California miner, we prospected the range of mountains at the head of this placer for the source of the gold; but with but little success, except as to the quartz mine known as La Mina de Salazar. Nature in her workings in ages past had covered up all traces of quartz-ledge, pockets, and auriferous slates from the pick and hammer of the surface prospector. The quartz mine spoken of, is traceable along the head of the placer for over a mile, and has been worked to a depth of about 200 feet by a main shaft and well prospected in other portions of its length. From history and tradition, as well as such samples of the ore as we could obtain, we did not feel tempted to pump out a mine the average yield of which did not exceed \$25 per ton.

The topography of this placer, as well as that of Cienega, is much like, in appearance, the "hog-wallows" met with on the plains of San Joaquin valley, except that they are on a much grander scale, with shallow and deep pits alternating in every direction with little and big mounds of earth, turned up by the industrious miners. Many of these pits and mounds are covered with grass, while the hummocks often support trees generally of the *Mesquit* and *Palo verde* varieties, whose growth must have commenced in the early part of this century.

From the great scarcity of water at Los Llanos, we resolved to camp and make headquarters at Cienega, where the little lake in the center of the deserted and fallen city gave us an ample supply for man and beast, as well as the means of making tests of the value of the grounds, by the use of water.

In our survey of Cienega we took an extent of ground about equal to that of Los Llanos, estimating the workable grounds at about 30 square miles.

The natural facilities for hydraulic workings of the Cienega placers are very good indeed, the greater part of the grounds being located on plateaus some hundreds of feet above the town site, and connecting with the valley below, by, in many cases, precipitous gulches.

In a general way our prospects, at first at Cienega, were made in a manner similar to those at Los Llanos and with about the same results.

In any event our work here resulted in the formation of the Cienega Placer Mining Co. in San Francisco, Cal., with the shipping from that city of such machinery and material as would enable us to test the value of the placers in a practical manner. Our first effort in this way, was to turn a small kiln of lime and sink a curved well in the quicksands of the Arroyo Grande, which swept around the northern line or foot of the placers from the mountain range on the south, the Arroyo, trending northwest and then south west into the plains. The curved well was laid in mortar, with stone, was circular in form and six feet in diameter. This we started on a circular form or base of plank, using, of course, only the rim, one foot wide, making the well from out to out, eight feet in diameter. We laid up the wall on the plank form and commenced shovelling the sand from the center, the curb sinking slowly as fast as the excavation was made, and perfectly protecting the workman from any but a gradual flow of sand at the bottom of the well and from without. The stone curb was being continually added to from above, until its weight became such that it was not a question of safety, sinking in quicksand, but one of keeping the curb from sinking too fast, and forcing the loose running sands up through its center, and delay the men in their work. The well was put down through the sand in this manner for 32 feet, when bedrock was reached, a conglomerate formation, and with a flow of four to five miners' inches of water. Having a steam boiler on the surface, and locating a Knowles No. 10 steam

pump near the well in an adjoining excavation, and some 20 feet below the top of the ground, it was an easy matter to connect a suction pipe with the bottom of the well and keep it free from the flowing water. In this way we got down about 40 feet, and having found no gold at surface of bedrock, or in the rapidly hardening conglomerate, we stopped sinking and devoted our attention to raising the water from the well, through a seven-inch pipe line in a string of sluices we had put up on the placers, about 50 feet above us and some 800 feet away.

Our sluices were laid in the regular way, with not so much fall, perhaps, as used in California, as we had no gravel to contend with. They were well provided with riffles and quicksilver, and with fully 12 to 15 miners' inches of water, pumped up from the well at the arroyo, we commenced the practical prospecting of the placers of Los Llanos and La Cienega.

Employing several teams to haul the dirt and sands from many different parts of the grounds for testing, we weighed off the dirt into tons of 2000 pounds, putting it through the line of sluices in lots of 5, 10 and 20 tons and cleaning up each lot separately. In this manner we must have made 100 tests, in every case meeting with returns that would be considered a bonanza by the hydraulic miners of California. Our returns averaged 10 cents per ton of 2000 pounds, or about 20 cents per cubic yard. The sand that had been worked over and over by the Mexicans and Indians by dry methods was the only material we tested, as we had become educated by experience to believe that it would be singular ground containing gold, that would escape the hawk eyes and expert hands of a Mexican or Yegui Indian. Again, much of the dirt put through the sluice line came out in small undissolved lumps, and which, after a good soaking in water, we found would yield gold in about the proportions given above.

The gold extracted was worth \$19 per ounce, and was generally of a granular and ragged character, there being, as far as I know, no flour gold found in the districts.

It will be seen that there are some wonderful possibilities in working these placers in a large way, and that there are nearly one hundred million dollars in gold in the grounds, allowing 60 square miles as the extent of the two placers and the dirt and sands to be five yards deep and the value per yard to be ten cents.

These figures were of interest enough to cause a diligent search for a water supply, which was found about 30 miles away, near the city of Altar, in the Altar river. Probably 2000 miners' inches could be obtained from this source, and by piping, give a head at the highest ground on the placers of 300 or 400 feet. As for labor and living supplies, they are cheap and abundant, with a climate much like that of our own State, although somewhat different in time and term of rainy seasons. The rains occur there twice a year. Two to three months of what is known as our midwinter, and about two months in midsummer. During these periods, it is quite a deprivation to the dry washers, the damp sands and earths making the use of the machines impossible. Yet again it has this advantage, that the rains readily dissolve the lumps not previously powdered by working, rendering a rewashing of the grounds, when dried by winds and sun, perfectly practicable and profitable.

In regard to the Mexicans themselves, I can cheerfully testify to their almost universal generosity and hospitality, that needs but a courteous return, to make them everlasting friends. The millions or so of dollars required to place the placers in bonanza, together with the uncertainty of our obtaining exclusive title and possession of these valuable mineral lands, forced us to reluctantly abandon the enterprise.

CHARLES MARION TYLER, M. & M. E.
April 9th 1891

The Newton Copper Mine, Amador Co

[From our Travelling Correspondent.]

EDITORS PRESS:—The Newton is in charge of Mr. J. A. Ferson, who is well known as the Superintendent that took the Union copper mine of Oalaveras county, when it was but a shaft full of water, and carried it through to an average yield of 100 tons of ore per day, and is now the most complete copper plant on the coast.

In this connection I wish to correct an error in a former article by myself on the Oxford Copper Smelter at Copperopolis, where I am made to say that the capacity of the Smelter is 10 tons a day. It should have been 10 tons to a charge or about 100 tons a day. But to return to the Newton. [The main shaft on the Newton is down 433 feet, with drifts run north 385 feet.

The vein averages four feet. On the lower level the ore carries 14 per cent of copper; the other levels carry from 7 to 30 per cent of copper.

All this time there is 11,000 tons of roasted ore in process of leaching and 5000 tons of raw ore on the dump. The mine is equipped with all the necessary buildings; and a complete hoist to go 1000 feet in depth.

The property covers 93 acres—U. S. Patent—which gives 2000 feet on the vein.

There have been expended on the mine over \$100,000. Of the ore on the dumps 4000 tons can be smelted and he made to yield \$60,000 clear of all expenses. About \$25,000 would

carry the mine through to a daily net income of \$300. The plant may be sold to be idle outside of leaching. Considering the value of ore on dumps, the size of vein, per cent of copper and the very small price asked for the mine, I know of nothing that promises as large returns for amount invested.

E. H. SCHAEFFLE.

Smartsville, Yuba County.

[From our Travelling Correspondent.]

EDITORS PRESS:—Smartsville's past record as a gold producer may not be again equaled unless the restrictions on hydraulic mining be removed, but a much larger percent of the gold extracted will be saved by the present methods of working, and the field left for a generation. The old channels are deep and the gravel banks immense, with the gold distributed throughout the entire body. With the hydraulic the entire body will pay handsomely; but to conform to the present conditions, it is not possible to work to a profit more than a few feet of gravel next to the bedrock. This is drifted, crushed, and then ground in an arrastra to polish the gold and remove the film that prevents the golds amalgamating. After grinding, the contents of the arrastras they are discharged and the gold caught in sluices. In all gravel or cement deposits, there is a large percent of waste which is usually crushed.

The Snodgrass Patent is a step in that direction of better results, but there is still room for further improvement. Two methods suggest themselves: First to employ pickers like the slate pickers in the coal mines, to pick out the waste boulders as it moves down over the screen; or second, and perhaps better, to have the cement feed into a revolving drum, like the Snodgrass, and discharge on to a grizzly. The revolving drum would loosen the cement from the cobbles and the grizzly separate it, so that the cobble would all be discharged by itself and the gold-bearing cement alone, to be fed into the battery or arrastra, and thus by concentrating the material increase the capacity of the plant ten fold, and lessen the cost of operating correspondingly. It is a question which is the best method of amalgamating this class of gold.

At Forest Hill, on the May Flower, the pulp, after it leaves the battery, flows over a series of polishing bars and it is claimed that the results are very satisfactory. Here at Smartsville the arrastra is used. If the cobble was all removed, the material thus concentrated run through double discharge batteries, and the pulp from the batteries allowed to flow into a system of continuous feed arrastras with plates at the discharge of the lower arrastra, the whole operation could be made automatic, the product handled very rapidly, and about all the gold contents of the cement saved. At this time the principal work at Smartsville is confined to the Excelsior and Blue Point properties.

The Excelsior W. and M. Co.'s property, W. S. Stewart superintendent, is locally known as the Ayer mine and it is situated on the Pioscene Yuba channel at Mooney's Flat, two miles northeast of Smartsville. This channel is here 75 feet in width and is opened and operated by a 75-foot shaft, with gangways driven 300 feet on the channel. About ten feet of the cement, next to the bedrock, is mined. This gives an average of \$3 a ton by arrastra process. The mine's output at the present time is 40 tons a day.

The Blue Point mine, H. B. Wheaton lessee, is opened by an incline shaft, the channel being about 50 feet below the mouth of the shaft, which is run from the bottom of the old face secured in hydraulic times. Sixteen feet of the cement gravel next to the bedrock is worked, and yields from \$2.50 to \$3 a ton. About 70 tons of cement is worked each day. The cement is broken up, run through a rock-breaker, and then fed into arrastras, where it is given just sufficient water to bring it to the consistency of a pudding, when it is thoroughly ground and discharged through a side-gate into a set of sluices. The present operations are profitable, but when contrasted with "the days of old, the days of gold, the days of '49," when the hydraulics brought down the bank and liberated the gold from thousands of tons of gravel each day, it is like trying to accumulate a million by saving a penny each day. The gold is here, millions of it. Just how long it must lie here, benefiting no one, is a question for our engineers to solve by providing a way that will again permit the use of the hydraulic.

E. H. SCHAEFFLE.

White Oak District, N. M.

EDITORS PRESS:—The mines of the White Oak district are now in a very prosperous condition. In my last letter, I spoke of the new discovery on the Old Ahe property, made by Wm. Watson, one of the owners. At that time, I could only speak of the new prospect as it appeared at a depth of a little more than 35 feet, and of the results of the first mill-run of 46 tons, which cleaned up \$33.50 per ton. Now the working shaft is down over 200 feet, with six levels open, and the ore body developed over 200 feet along the lode. The width varies from 30 inches to 11 feet, and the grade of ore has so increased with depth that the average mill "clean ups" have been over \$50 per ton.

For two months or more, in fact up to March

1st, the owners ran the old ten-stamp mill east of town. The mill was always of very small capacity for its size and is nearly worn out. While using that mill, they could only get through from eight to ten tons in 24 hours. Since March 1st, they have been running the North Homestake mill, that mine being for the present idle. They manage to get through 20 tons per day. The owners will bring in and erect a fine mill of their own the present year, intending to have it in full operation by the end of September. Mr. Watson, who is the mining man of the parties interested, and managing owner, will visit California this spring to inspect recently erected gold mills there, with a view to the adoption of every recent meritorious device which tends to increase efficiency or reduce expense. When he goes to the coast, I shall take the liberty of asking for him your good offices, in the way of facilitating the objects of his visit.

Mr. Dye the managing owner of the Lady Godiva has been steadily employed in developing his fine property, adjoining the Old Ahe northwardly. In this mine, there are two veins, the Lady Godiva in the working shaft, and the No. 1, 50 feet west of that. Levels have been run on both at the 450 level, and stops opened on the No. 1. These veins while pocket yield ore of a very high grade. Dye is sinking a winze from the 450 level on No. 1, and will sink the working shaft at once. Other property adjoining, chiefly owned by Mr. Dye, has been long in litigation. All of that which affects the working of the property, has been settled favorably to Mr. Dye's interests, and such being the case, extensive workings upon ore bodies of known value, in that property, will shortly be commenced.

The South Homestake is working a considerable force of men, and is dumping ore of good grade. The North Homestake is idle, the owner being engaged in exploiting and equipping another mine in California, and not being able to give this his attention. The stoppage will, however, be temporary. This great property has a good many thousands of tons of good grade ore blocked out ready for stoping, and it is safe to say that it will not remain idle a day longer than the owner can arrange his affairs so that he can give it his attention.

We may then look for a prosperous mining year in our chief mining district, and may confidently expect our production of the yellow metal to be in 1891, about three what it has hitherto been.

I will from time to time report prospects and it is in the air, that I may be able to chronicle the development of yet new mines in that old district. In the other mining district of this county, but little is now doing. The Parsons mine in the Bonita district is idle. On the death of the discoverer, a sole owner, it fell into the hands of his heirs, none of whom knew anything of mining, or of the mining regions. The management has not been of the best, and the property is understood to be so far entangled, that it may remain idle a long time. With the chief property in the district in this condition, a cloud has fallen on the camp.

Lincoln, N. M., April 7, 1891.

Daily Weather Maps from the Signal Service.

EDITORS PRESS:—The inclosed map is a copy of the first issue of the new daily weather map which will be published regularly at this office.

For the present the maps will be published from the morning reports, at about 10 A. M. If it is found necessary and advantageous to public interests, a second daily map will be published from the evening reports, about 7 P. M. These maps are intended for free distribution to commercial associations, educational institutions, public libraries and individuals. The edition will be limited in order to avoid unnecessary expense. Requests for the map should be addressed to the undersigned and give particular reasons for receiving the publication. The necessity for such a requirement is evident, as the maps must be furnished to those who need them most and can make the best practical use of them. There are two important uses to which the daily weather map can be applied.

1st. To obtain information as to the daily forecasts of weather and temperature for the Pacific Coast States. In this case it is necessary that the map should reach its destination sufficiently early to make the forecasts available within the period for which they are made. It is evident that the use of the map in this respect will be quite limited, owing to the want of sufficient railway facilities for distribution by mail from San Francisco.

2d. To study the weather conditions of the Pacific Coast States from the standpoint of synchronous observations. The daily weather map is practically a photograph of certain atmospheric conditions prevailing over the region represented by the map. It affords the very important advantage of studying the weather of a place in the light of extensive surrounding conditions that influence it. By such investigation, the reader of the daily weather map becomes able to prognosticate from the local conditions at his station, and to have a better understanding of the general forecasts issued from the central office. In this case the weather map can be kept in permanent file for future reference to great advantage. Any particular storm or change in weather conditions can be studied at leisure. This new publication has been inaugurated to give the people of the Pa-

olico Coast every practical advantage of the Signal Service now provided by the Government, and which is enjoyed by other sections of the country.

Defects appear in the first edition that experience and better facilities will gradually eradicate. The public are kindly invited to make suggestions regarding the character and extent of the data published that will tend to enhance the practical value of the map.

JOHN P. FINLEY,

Lieut. 19th Infantry, S. O. in charge,
San Francisco, April 14th.

The World's Fair.

By a law enacted by the recent Legislature, the Governor was authorized to appoint a Board of World's Fair Commissioners as a controlling body concerning all matters wherein this State is interested and to control the expenditure of the \$300,000 appropriated for California representation at the Exposition. Governor Markham has named the following gentlemen to constitute the board: First district, John Daggott of Siskiyou; Second district, Robert Murray of Nevada; Third district, A. T. Hatch of Solano; Fourth district, Irving M. Scott of San Francisco; Fifth district, James D. Phalan of San Francisco; Sixth district, L. J. Ross of Los Angeles; Seventh district, Thomas H. Thompson of Tulare.

These commissioners have been selected to represent the State geographically and her leading industries as well. Live-stock, mining, fruit-growing, manufacturing and general farming and progress in land development are believed to be well covered by the appointments made, and certainly the men chosen are widely known, not only in their own regions, but over the State at large.

The progress of the World's Fair enterprise seems to be fairly active. The National Commissioners from California, who are now in Chicago, do not agree among themselves as to who should be chosen for the headship of the horticultural department of the fair, the candidate who has been generally appointed here has apparently been thrown out, and it seems to us altogether unlikely that the appointment will go to a Californian in view of this discord among our representatives, but this point is not settled yet.

According to recent reports the different States have appropriated nearly \$1,500,000 for the purposes of State exhibits, and there are other amounts still pending in the Legislatures of the different States. So far the California appropriation of \$300,000 is the largest made by any State. States which have defeated appropriations are as follows: Alabama, Arkansas, Kansas, Oregon, South Dakota, Tennessee and Texas.

Various comments upon the anticipated influences of the great fair of 1893 are being made. The following is a general view of the case which certainly has much force. Greater than even the reciprocal advantage of education between producer and manufacturer, American and foreigner, the Exposition as a unifier of the people of the United States will amply repay whatever money be spent in its preparation. East and west, north and south, the people of this country are gradually becoming provincialized as the process of local development creates new centers of interest apart from the capital or metropolitan cities. In the crowded cities of the East hundreds of thousands of people live and die in the belief that the Great West is still a rowdy wilderness peopled only by uncouth, semi-barbarian, and in like manner in many Western cities the idea of Eastern civilization is indelibly associated with that of effeminacy. North and South in like manner are each of them unknown countries to a large percentage of their opposite people. To efface this sectional feeling, the World's Columbian Exposition will be an agent of incalculable potency. Mingled together in one common ground, unnumbered in honor of an event equally beneficial to all, stimulated by individual interest and local pride, protectionist and free trader, manufacturer and farmer, Easterner and Westerner, Northerner and Southerner, American and foreigner will join hands to make the World's Columbian Exposition an event of which not only the American people, but the world itself and the great nineteenth century may justly feel proud.

Figures of the possible attendance at the World's Fair are also being indulged in. The attendance at the Philadelphia Centennial, as shown by the number of admissions, was 9,910,996, and at the recent Paris Exposition, 28,149,353. Large as was the latter, it is expected that the attendance at the World's Columbian Exposition will equal it.

It is telegraphed from Chicago that Commissioner De Young has selected as a site for the California building $1\frac{1}{2}$ acres of land nearly opposite the present boatwharf in Jackson Park.

A GORGEOUS MINERAL PALACE.—A meeting of the Directors of Colorado Mineral Palace Company was held in Pueblo, Colorado, last week, and bids were received and contracts let for the thorough completion of the Palace building, the work to be commenced and executed without delay. It is expected that everything will be ready for the opening of the exhibition to the public of the greatest collection of minerals in the most gorgeously handsome building ever attempted in the world, some time in June next, the exact date to be hereafter announced.

That Lost Mine.

Several miners have come back from the Pahrump valley, east of Death valley, where the recent discovery of gold-bearing quartz was made by the Montgomery prospecting party, and the lost "Breyfogle mine" was supposed to have been found. The quartz shown in San Francisco was quite rich, but later reports are not so favorable. Henry C. Callahan, late superintendent of the Eagle Bird or Diamond D mine, Nevada county, was one of the party who recently visited the camp, and he tells the Grass Valley Union that they found the camp and examined the lodes upon which prospecting had been done. The quartz prospected well in gold. The lodes were inclosed between lime and quartzite formations, the quartz being white and free from other mineral and of a character that the miner would call "angry." The evidences were not favorable of the lodes being true contact veins that would hold out in depth, but of that there has not been sufficient work done to determine. The Montgomery party had made a number of locations and had covered all the ledge to be found in that immediate section of country. This company had fitted out in Calaveras county, and Mr. Callahan says it was the best-equipped prospecting expedition he has ever seen, and its work was conducted on a very efficient plan. They had a large outfit, an abundance of supplies and a large transportation force of men and pack-animals. They had one main camp from which men and animals were sent out in different directions, and subordinate camps established, and from these, prospecting operations were extended in different directions, that enabled them to cover a large extent of country in their prospecting operations and to secure each locality as gave any promise of future value.

At the Montgomery camp, the water has to be brought from a distance of five miles, but taking that district generally, the water supply is good. At the northern end of the mountain range there is good timber, and one or more sawmills have been established in that section. There are now 60 prospectors in the new field. Mr. Callahan is not enthusiastic in regard to this new mining field, although there have been some excellent prospects of gold obtained. The country is isolated, and a long distance from a base of supplies, and development work can only be successfully prosecuted by strong companies. It is not a field for poor prospectors, and men who are not well supplied with means have no inducement to go there at present. A railroad survey has been made from Pioche to California, which skirts the Death valley region, but not immediately on the border of the valley, and should the road be constructed, it would be within five miles of Pahrump valley, and would afford an opportunity for the opening up of the mineral resources of the region, which, under present circumstances, is impracticable.

Electric Railroads.

After a great deal of opposition and discussion, the Legislature finally passed a bill permitting the use of electricity on street railroads in this State. The main objection came from San Francisco, where they objected to the use of overhead wires for these roads. This week an order was introduced at the San Francisco Board of Supervisors meeting, and passed to print, prohibiting the use of poles or any other above-ground apparatus for the propelling of street cars by electricity within the following limits: Commencing at the west line of Van Ness avenue and the bay, thence direct to Market street and across to Eleventh, thence to Bryant, to Tenth, to Channel, to Potrero avenue, to Alameda street, easterly to Eighth, to Channel, thence along Channel to the water front, along and around the water front to the point of beginning. The order also rescinds all permits hitherto given for the use of overhead poles, wires, etc., and provides for the forfeit of franchise by any company using them.

These limits include all the main central portion of the city, but not the outlying districts. Judging from the vote by which the order was passed to print, it is probable it will be eventually adopted. The effect of the order will be to stop such work as has been done at night on the water front of late, where an elevated railroad is being built.

As the law now stands, each California city may itself permit overhead wires or not, as it chooses. It is evident that the San Francisco officials do not want roads of this character here under that system in the main portion of the city.

ROCK BLASTING BY ELECTRICITY.—Messrs. James Macheth & Co., 128 Maiden Lane, New York City, have just issued a neat little pamphlet on "Rock Blasting by Electricity," together with illustrated catalogue and price list of Victor elastic platinum fuses, electric blasting machines, electric fuses and blast testers, wire reels, battery testers, insulating tape, leading and connecting wires made by them. The text which shows evidence of being carefully prepared is generously illustrated, and contains a great deal of valuable information for blasters in the use of the company's electric blasting appliances and rock blasting by electricity in general. This pamphlet can be had upon application.

Academy of Sciences.

The museum of the Academy of Sciences is approaching completion. Considerable work has to be done before the specimens are ready for exhibition. The collection of birds presented by Mrs. E. B. Crocker of Sacramento is already in place in the gallery. The Ward collection will be prepared for exhibition as soon as possible. The collection of birds prepared by the scientists of the Academy is still in the boxes, and will not be unpacked for some time. The big elephant, which is a fine simile of one obtained from the bank of the Lena river, in Siberia, will be on exhibition. The curator in ornithology is busily at work, as well as the botanists of the Academy. Large additions have been made to the botanical collection lately, and the collection is now one of the finest in the United States. The rooms are admirably adapted for the purposes for which they were designed. The museum building is on the rear of the lot. The front building was first completed and already brings in considerable of an income. The building is as nearly fireproof as it is possible to be. The materials are iron, stone and brick. The galleries are all of iron and the staircases also. The library is very valuable and many rare books are to be found in the collection.

Walter E. Bryant, Curator of the Department of Animals and Birds at the Academy of Sciences, recently discovered a new species of hare, to which he has given the name *Lepus insularis*. It is found only upon the island of Espiritu Santo, in the Gulf of California, off La Paz bay.

The hare is black, and it is rather larger than those found in California or Lower California, but possesses all the characteristics of the genus.

"This hare," said Mr. Bryant to a reporter, "is a great find. The Smithsonian Institute several years ago received two skins of the species preserved in alcohol, but overlooked them, and it has been left to our Academy to describe and name the hare."

"A curious feature about the species is that its color adds a proof of the opinion held by many, that color in wild animals always accord with the color of the cover in which they live. Trout are dark or light, gray, black, yellow or green, in accord with the general color of the bottom of the stream in which they may be found. The ptarmigan of Alaska is a rusty brown bird in summer when it lives in edge and brush, but in winter is snow white. The same is true of the Arctic hare."

"The new species of hare is so like in color to the dark granite rocks on Espiritu Santo as to be indistinguishable when at rest. When it comes down from the rocky retreats into the grass land to feed it can hardly be seen, but at the slightest alarm it runs to the rocks and is lost to sight, because its black color is like that of its surroundings. In lower California the hare lives on sand deserts and is light gray, just like the sand and scant herbage about them."

THE ONTARIO SILVER MINE.—The total output of the Ontario Silver mine near Park City, Utah, from the starting of the new mill Feb. 1, 1877, to the end of 1890—fourteen years—was 341,497 net (dry) tons of ore out of which was obtained 24,398,359.99 ounces of fine silver, and for this silver the company received \$24,607,292.88, a fraction of a cent more than \$1 per ounce. As the bullion was sold as produced each month, this is as fair an average of the price obtainable for silver during the last 14 years as it is possible to obtain. Out of the money received the company paid up to January 1st of this year 175 monthly dividends of 50 cents per share, aggregating \$11,525,000. Of these 175 dividends 64 were paid on 100,000 shares, 111 were paid on 150,000 shares. The stock was increased by 50,000 shares to pay for new ground in 1881 or 1880. The average yield per dry ton was \$72.06. It would be hard to say correctly what percentage of moisture should be added to ascertain the number of tons of ore as raised out of the mines, but probably about 15%. For a considerable part of the period under consideration the moisture was 25 per cent of the weight. Assuming that it was on the average 15 per cent, the output was 392,721 gross or wet tons, and the yield per wet ton was \$61.26. The total output of the Daly silver mine, an extension westward of the Ontario from January 1, 1885, when it began to produce, down to the end of 1890, was 120,706 net tons, from which was obtained 5,530,830.87 ounces of fine silver; this silver sold for \$5,106,684.69. Out of this money 46 dividends were paid, aggregating \$1,762,500; the average yield was \$42.30 per dry ton; or, adding 10 per cent for moisture, \$38.07 per wet ton.

IN THE FAR NORTH.—A new mining country is engaging the attention of the adventurous at present, and as soon as the summer season opens a rush for the new "diggings" is expected. It is the Kootenai-Flathead country, situated in Missoula county, near the Washington and British lines. The Flathead valley is said to be a rich agricultural country, coal is to be found in abundance and water communication is had with the coast by means of the Flathead lake, Flathead river and the Columbia river. In a short time the country will be traversed by two railroads. The Great Northern, which has its western terminus at Fairhaven, Wash., is constructing a road, and the Northern Pacific is building a road

from its main line northward to connect with the Canadian Pacific in the British possessions. The mines have never been fully developed, but the ore is said to be of a remarkably high grade and only the absence of transportation facilities has kept them in the background. The principal town is Demareville, which, although only one year old, has a population of nearly 2000. It is a frontier town, with all the attractions which the name implies, and "spring of '50" prices prevail. A new town has just been located by the Great Northern Railroad, and tenderfoot are settling up the country very rapidly.

THE DRUMMOND MINE, Marysville, Mont., produced in the last half year 42,753 tons of ore, worth \$4,526,576. The average cost of mining and milling per ton was \$8.30, a decrease of 89 cents per ton from the previous six months. The total output for last year was \$1,097,345.55. Four dividends of about \$34 each were paid the shareholders during the year, who now number 2890. The ore reserve on December 31st showed 187,200 tons in eight. The total lineal development of the mine for the year was 10,698 lineal feet, and the total lineal feet of development in the property at that date was 42,240 feet, or about eight miles. R. T. Bylles, general manager, and G. H. Robinson, deputy manager, have resigned, but have not entirely severed their connection with the company. Mr. Bylles is to be a director in London.

PLUMAS COUNTY SLICKENS.—A. E. Agassiz and Quincy A. Shaw have begun suit in the United States Circuit Court against John B. Sotton et al., for an injunction. The plaintiffs own 1500 acres of land in American valley, Plumas county, the greater part of which is protected from the overflowing of Spanish creek by embankments. The defendants own a placer mining claim farther up the creek, known as the Hungarian Hill gravel mine, and the plaintiffs say that the washings from this last mine come down the creek and threaten to inundate their land. Work has been stopped by the defendants for some time, but they are now preparing to begin work again, hence the suit to restrain them.

IRRIGATION ENTERPRISES.—Irrigation enterprises seem to be progressing vigorously at the South. It is telegraphed from San Bernardino that the pipe line to Alessandro is nearly completed and the water will be turned on next week. Nearly 500 laborers are at work putting in distributing pipe on the Alessandro tract, 80 miles of which is being laid. The Arrowhead Reservoir Company, organized in Cincinnati, with a million dollars capital, will commence work soon putting in a system of reservoirs in the mountains north of San Bernardino on the head waters of the Mojave river. Half a million will be put into the enterprises this year, and 80,000 acres or more will eventually be irrigated.

NAVAL OBSERVATORIES.—It is stated that many leading astronomers of the United States are uniting their forces and will memorialize the next Congress to transfer the control of the United States Naval Observatory at Washington from the hands of the Navy Department to the hands of a purely scientific and astronomical board. This is the outgrowth of dissatisfaction among the various observatories, growing out of the practice of the Naval Observatory of supplying telegraph companies with time signals for commercial use.

BALL BEARINGS.—Among the patents issued by the Patent Office on Tuesday, were 17 to George F. Simonds of Fitchburg, Mass. This is the largest number granted in a single day for many years, but the case is also interesting, because the inventor has, it is claimed, successfully solved the problem of applying the principle of ball bearings to the heaviest machinery. Hitherto it has only been possible to see these bearings on light machinery.

SULPHUR.—The Yuma (Arizona) Sentinel says: Lying to the southwest of Yuma, about 75 miles, on the west slope of the Coconino mountains, there is the largest deposit of pure sulphur that has ever been found on the American continent. It is situated on or in the side of a mountain, about one-half way up the summit. The deposit is about 1100 feet in length, 70 feet wide, and so far as opened is 40 feet in height.

BEETLES.—A Woodland scientist asserts that 20 different varieties of beetles are infesting that pretty little town. They come from the tule swamps in such swarms that sometimes the electric-light globes have to be cleaned. Chinese are employed for the work, and they pack the beetles into sacks and use them in compounding medicines.

WASHINGTON COAL OUTPUT.—The output of coal from the Newcastle, Cedar Mountain, Black Diamond and Franklin mines during March was 37,378 tons, as compared with 31,854 tons for February. The output at the Roslyn mines was 26,172 tons, a slight increase over that of February.—Seattle Post Intelligencer.

THE GRASS VALLEY TELEGRAPH says: Black sand from Dutch Flat will be worked at the new extraction works of this place. The black sand has gold in it and the extraction works will get the precious metal out so that it can be made into \$20 gold pieces.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

SUTTER CREEK.—Cor. Amador Ledger, April 12: The mining industry is moving along in the usual way. At the North Star they still have indications of ledge matter, but nothing to be elated over. They are still pushing ahead in the hope of encountering something. The Lincoln is running steadily, with prospects of continuing all summer. The sulphurets works are running full blast and in condition to run for a long time without repairs. The pipe for the Mahoney mine is laid and the work of getting the mill in repair is progressing as rapidly as possible. It needs a good deal of repairing, having lain idle so long. It will probably be a month yet before the stamps are ready to drop.

PLYMOUTH.—The Plymouth Con. Co. is all ready to start up 40 stamps, and will be pounding away on good rock before this is in print. The New London mine is still working away as usual, and it would be no surprise to this community to hear the stamps at that mine running before long. There will be a call for a meeting of the shareholders of the Bay State mine for the purpose of effecting an organization of the company and going to work before long. The stock is about all taken, and the assessment money will be paid in as soon as called for. There will be nothing to stop this popular mining venture from being in full blast by the middle of June. The Good Hope is lying still at present, preparatory to putting in some new machinery. Theo. Etling & Co. are making arrangements to start up the Mammoth. There have been some fine assays from rock taken from this mine lately, going as high as \$70 to the ton. There is a good deal of placer mining and prospecting going on in the near vicinity of Plymouth and considerable gold is being sold to our merchants.

VOLCANO.—The old A. P. Clough place has been sold to a San Francisco company. Work has commenced on the mine and machinery ordered for a mill, which will be built as soon as the material can be got on the ground.

Calaveras.

UTICA.—Angels Echo, April 9: The following-named gentlemen have taken a contract of sinking the Utica mine 230 feet deeper: T. C. Halstead, James Murray, John Doubt and Charles Smith. The shaft is at present 600 feet deep and when the contract is completed will be of course 830.

AT WEST POINT.—Cor. Calaveras Chronicle, April 12: Dull clouds of depression have been hanging over the sombre town of West Point since the closing down of the Riverside and Lone Star mines, but there are indications of these clouds drifting over, for it is rumored that these mines will resume work. The good and promising Lone Star mine will be worked in the future to some extent by Burleigh drills and great results are anticipated by good and practical miners, for it is the intention of the company, it is thought, to run levels and well develop the mine. The permanent and nonpareil mine—the Blazing Star—has been working all winter, with a small force, developing the mine by sinking and running levels. The mine has splendid indications of being a permanent and remunerative piece of property for many years to come. The last year has changed the mine beyond the most sanguine expectations.

MINE BONDED.—The well known Boston Mine, near Sandy Bar, on the Mokelumne River, which has been idle for many years, has been bonded to Mr. Kreling, of San Francisco. A tramway is being constructed from the mine to the Sandy Bar Co's mill on the Mokelumne River, for the purpose of transporting a hundred or more tons of rock to be tested, upon the favorable result of which a plant suitable to work the mine upon an extensive scale, will at once be put up. Col. W. T. Robinson is in charge of the present operations.

ANOTHER MINE OPENING.—F. J. Horswill has obtained the ground formerly belonging to what was known as the A. & B., or Arrowsmith mine, near the old "Flume House" site, on the "Poor Man's Gulch" slope. An incline is to be run. Steam hoisting works are to be put up, a road to the location is now being constructed, on the completion of which, the machinery will be laid upon the ground.

Inyo.

MINING PAYS BEST.—Independent, April 10: Chris Crohn discovered that farming in Sonoma did not pay and returned to Inyo last summer to resume mining. He has been engaged for several months past in developing the Augusta, a patented mine owned by him about 3½ miles north of Cerro Gordo on the Saline side of the ridge. A piece of ore taken from the ledge was brought to town to be sent below for assay. It is black metal and will assay at least \$500 per ton. A tunnel is being run on the ledge, and some of the ore is being taken out for shipment. The mine is likely to develop into a valuable property.

Nevada.

NORTH BANNER MINE.—Grass Valley Union, April 12: Some high-grade ore is beginning to show in the north drift of the North Banner mine, that gives the appearance of a new shoot coming in. The quartz is heavy with sulphurets and galena, and shows fine particles of gold, and its general appearance is excellent. The vein from which this quartz comes is 20 inches in size, and goes down below the floor of the drift. It was not expected that rock of such quality would be found at that point, as the pay shoot coming down from the levels above is farther to the north. The North Banner is certainly making an excellent showing, as it has entered upon the payment of monthly dividends, which are likely to be kept up for an indefinite time.

PROSPECTING AT SPENCEVILLE.—Grass Valley Union, April 12: From Pietsch, of the Spenceville Copper M. Co., the Union learns that prospecting operations are going on steadily in that vicinity on several claims. The lodes of that section contain copper, silver and gold, and the prospecting now being done is mainly on gold-bearing veins. The Champion is considered a very promising prospect, as it makes an excellent showing in the shaft that has been sunk on the croppings, and a tunnel is now being run to cut the vein at the depth of several hundred feet. The tunnel is now in a distance of

275 feet, with several hundred feet yet to be run. The vein assays high in gold and also contains silver. The Mammoth Co. is also running a tunnel, which is in a distance of over 300 feet; and work is being done on several other claims. All the development work is being done by tunnels. The Spenceville section has many mineral leads that prospect in gold, but the most attention heretofore has been on copper bearing veins, but it is believed the district will yet have its greatest prominence as a gold producing region. The Spenceville Copper Co. is regularly producing profitably in cement copper, and also in the production of mineral paint, furnished by the dump piles of copper waste of which the company has about 250,000 tons.

W. Y. O. D. DIVIDEND.—The W. Y. O. D. M. Co. has declared a dividend of 5 cents per share, amounting to \$1500. This is the second dividend declared by the company, and it is the expectation that they will be continued regularly each month, as the mine is making a continuous profitable output. This is being done with a small five-stamp mill, but the company is now engaged in putting up a new ten-stamp mill, which when completed will enable a much larger production, as the mine is sufficiently opened and the vein of size large enough to keep that number of stamps constantly employed. The ore of the W. Y. O. D. is of high grade, yielding about \$50 per ton.

NEW HOISTING WORKS.—Grass Valley Union, April 10: The Idaho Co. has put up a hoisting plant at the eastern end of its location and about 400 feet west of the line of the Maryland claim. This is over a prospect shaft that was sunk at that point and where a strong vein is shown. The shaft is now being strongly timbered and will be sunk to prospect the vein in that part of the location, which is over 2000 feet distant from the main hoisting works and mill. The hoisting and pumping will be done by water-power, which will be obtained from the Idaho pipe line, which passes close to the new works.

STRIKE AT THE DELHI.—Transcript, April 11: A four-foot ledge of very rich ore was struck Thursday night in the lower tunnel of the Delhi mine near Columbia Hill, and there is much excitement over the development. On two or three occasions recently, rich finds in the tunnel have been reported, but they did not prove extensive. It is now, however, certain that the main formation which proved so valuable in the upper workings has been reached. There are now 15 or 20 men employed at the mine, but as soon as the tramway now in course of construction to connect the mouth of the tunnel with the mill is completed the services of three or four times as many will be required.

SECURED WORKING CAPITAL.—Grass Valley Union, April 10: George F. Jacobs, who is to be Superintendent of the Manzanita gravel mine, at Nevada City under the new company organization, has sold 20,000 shares of the stock, which was the amount set aside to raise a working capital. The Manzanita, that is on the same channel as the Harmony, which is now giving fine prospects, is to be worked by drifting, and the company is confident that it will renew the profitable output of former days when it was operated as a hydraulic mine.

Mono.

THE MAY LUNDY.—Homer Mining Index, April 11: In reply to inquiries we will say that we are not informed as to the intentions of the May Lundy management. Nothing is being done at the mine now, though we should think they would be somewhat interested, considering the promising condition of mines on the south, and feel themselves warranted in starting work, on a small scale at least. The mine is still a good one, having never been systematically worked, but only outrageously gouged into the semblance of a rabbit warren. It has been the foot-ball of masterly incapacity and stupid inexperience, yet there are lots of gold left, much more than if the mine had been properly developed. A good deal of the ore extracted was worn out before it reached the dump, being handled so many times. If the management will give us the sweepings, we will contract to clean out the accumulated waste and debris, or dispose of it in some manner that will make the mine halfway presentable. From the clean-up we could obtain a nice little wad of gold.

Placer.

FOREST HILL.—Placer Herald, April 11: The Gray Eagle mine, located a short distance below Forest Hill, is developing some good gravel. The upraise which was mentioned in the Herald a few weeks ago as being made 1670 feet from the mouth of the tunnel, has been completed. It cut through into the gravel 168 feet above the tunnel. It was found to be too high, as where it broke through, the bedrock was pitching pretty steep. Down 19 feet from the top a drift was run into the channel, and it, we understand, is high, but it developed some gravel which from the prospects will pay \$3 to \$4 to the car.

Plumas.

THE DRURY MINE.—Greenville Bulletin, April 8: The Drury mine, now owned by Standart & McGill, will soon be operating in full blast. The future of this property was never brighter. In the lower tunnel there is said to be a large quantity of high-grade ore. The Bulletin has always maintained this to be a big property. The experience of the past few months is proving this view to be correct. The company owns back of the Drury the Pacific and the Forest King, which, doubtless, are parts of the same lode cut by North canyon.

Sierra.

TRAMWAY.—Mt. Messenger, April 11: New machinery for the tramway at the Mountain quartz mine, to replace that which did not work, has been shipped from San Francisco.

Siskiyou.

GRAVEL DEPOSIT.—Siskiyou Telegram, April 11: Mr. L. A. Lash, of the Lee, Lash & Parlin blue gravel mine on Greenhorn, is very enthusiastic over their find. In a conversation with him last Sunday, he expressed his entire confidence in the permanency of this rich gold deposit and expects that when their new machinery will be in place and in working order, that, owing to the increased facilities, for working, the mine will pay much better than at present. They have but very little trouble with water, and it is not found necessary to work the pumps over a few minutes each day. The gravel is found below a formation of sandstone, which accounts for it not being worked years ago, as whenever the miners struck this formation they always stopped, supposing that they had found bed-rock and could

go no farther, until, at last some miner, to satisfy his curiosity, pushed on through the sand stone, and discovered what we now call blue gravel. It is more than likely that this same valuable deposit exists in many other parts of the county, where its presence is not now suspected. The discovery of a blue gravel mine near the Black mountain, nearly half way between Yreka and Henley, goes to show that the Greenhorn lead and that at Henley is the very same, and we may expect that every foot of ground between here and there will be claimed in a short time, and some great bonanzas discovered.

BLUE GRAVEL.—Yreka Journal, April 8: The Yreka Blue Gravel M. Co. has sent George Kenyon to S. F., for the purpose of securing artesian well boring machinery, to be used in prospecting for blue gravel south of Yreka. He will also purchase a new steam engine and pump for the Lee, Lash, Parnell and Kenyon blue gravel mine, of great capacity, to take the place of the machinery now rented from Scheld. The blue gravel mine of Lee, Lash & Co., at Greenhorn, still continues the usual average, except last Wednesday, when it paid \$40 better than general. The gravel taken out yields not less than \$125 to \$150 per day, most of the gravel being very tough and hard to dig. As the men progress in extending the drifts, they find the bed rock raising a little occasionally, with a yellow gravel in shallow places, which pays just as rich as the blue gravel. Not more than two-thirds of the pay gravel can be washed at present, on account of its sticky nature, but it dissolves easily on exposure to the sun for a number of days.

QUARTZ.—The miners at work in the Spencer & Co. quartz ledge on Humbug, are down about 200 feet, and find the ledge varying in width from a foot to four feet wide, with well defined walls, every pound of the quartz taken out paying well. W. D. Shelly's portable engine, from Scott Valley, is now being fixed up at Nerhass & Harmon's shop, for use in running the quartz mill moved from Yreka Flats to Long Gulch, at upper end of the flats, and as soon as the batteries are set up, the mill will be started, with an abundance of quartz on hand to keep going all summer. Charley Abbott is now sinking down on his ledge at Greenhorn creek, which paid so well last summer, to find where it was broken off, as the croppings on surface shows the ledge had been pinched out and thrown over flat. The indications in the bed rock of shaft give promise of a rich ledge below the surface. Van Nader, who has a quartz ledge at Spring Gulch, on Yreka Flats, northwest of Yreka, has been taking out some very rich specimens lately, the gold running through the quartz like wiring, fine samples of which can be seen in the mineral cabinet at Ed. Herr's saloon in Wetzel's building. Van Nader has evidently struck a very rich pocket, which may develop into a permanent ledge as the work of opening his claim progresses. He has realized considerable gold already, by pounding out the quartz, many specimens being pure gold. Louis Guilbert, who has been sinking a shaft to bed rock in the Kidore Hills, about 3 miles south of Yreka, struck a heavy body of water at 65 feet, and is now making arrangements to put in a pump that will prove effective in keeping the water out. Louis Nerhass owns several acres of land, or a farm, on Greenhorn, adjoining the Lee, Lash & Co., blue gravel mine, near the Greenhorn school house, and may become a millionaire in the near future, as the blue gravel channel no doubt runs under the foundation of his ranch. He intends to have a well bored down to ascertain if blue gravel exists there, when the new machinery sent for arrives from below.

HORN BROOK.—Cor. Yreka Journal, April 8: The gravel in Jillson & Co's. mine is quite soft, pipes and "washes" very freely, and as rich as ever. In their tunnel, 180 feet long, the gravel is as blue as indigo, and easy picking ground. Mr. Jillson thinks he will have 100 feet more to run before striking bedrock. The gravel already shows prospects. The Black Jack is prospecting better, the gravel at present being good for six dollars per ton. This company will, probably, in the near future, put up extensive works to crush their gravel. The Portland Company's shaft is down 40 feet. J. W. Luten is in 138 feet, and expects to strike gravel in the next ten feet. Captain Wilbourn is letting a contract to drive his main tunnel. A report is circulated in town this week that George Bar has struck rich gravel on the south side of Black mountain, and about half way between Hornbrook and Yreka. Mr. H. C. Babcock has purchased a half interest in the Nels. Thompson mine, and will begin development work. A company of eight Hornbrook men have organized and located 160 acres of blue gravel, and will prospect it thoroughly with a diamond drill. They are now negotiating for a diamond drill and will have it in operation by the first of May. This property is located in Rocky gulch, and none richer was ever worked in Siskiyou county. Everything bespeaks success to them, for a more desirable location could not be found. Hill & Co. have gravel in their tunnel with bedrock pitching, and they expect to reach the channel. Hazlett & Jacobs are crosscutting in the California Queen, with favorable indications of soon striking the ledge. Jones and Hazlett are receiving encouraging news from their Hungry Creek quartz, the ledge being both strong and rich.

Trinity.

THE THANKSGIVING MINE.—Journal, April 11: W. F. Arnold informs us that the outlook for the Thanksgiving mine at East Fork is very encouraging. Since he has taken charge of it he has opened up a body of ore that will keep the mill running for several months. This property has been lying idle for some time, in fact the most of the time since Mr. Peterson left it, but there will probably be quite a stir there this summer.

Tuolumne.

GOLDEN GATE.—Tuolumne Independent, April 11: Supt. Loftus of the Golden Gate mine informs us that their new water-power is in operation and that the reduction works are being enlarged; also, that grading has commenced for 10 additional stamps, making a total of 20.

NEVADA.

Washoe District.

CONS. VIRGINIA AND CALIFORNIA.—Virginia Chronicle, April 11: There has been extracted from all parts of the mine during the week 1516 tons of ore, which were shipped to the Eureka mill. The average assay value of all of the ore worked at that mill during the week (1525 tons) was \$34.10 per ton.

OPHIR.—The upraise started in the drift run south from the drift run west from the winze, 122 feet below the sill floor of the 1300 level has been carried up 16 feet, and some ore has been extracted therefrom and stored in the mine, the average assay value of which is \$24 per ton.

UNION CON.—East crosscut No. 2 on the 1465 level, started from the north lateral drift at a point 200 feet south from the south boundary line of the mine, has been extended 24 feet; total length, 794 feet, continuing in a hard porphyry formation.

MEXICAN.—The east crosscut No. 1, started from the main north lateral drift at a point opposite the west crosscut No. 1, has been extended 23 feet; total length, 631 feet, passing in porphyry interchangeably hard and soft.

EXCHEQUER.—East crosscut on the north line, 600 level, is out 161 feet; face in porphyry.

CROWN POINT.—The south drift on the 300 level is out a total distance of 102 feet having been advanced 26 feet during the week. The face is in a mixture of clay, porphyry and low-grade quartz. The west crosscut, 1000 level, has been extended 25 feet, making its total length 50 feet. It has passed through low-grade quartz and clay, and has reached what is believed to be the footwall. Have been engaged in timbering and repairing the 1100 south lateral drift where necessary.

BELCHER.—The south drift from No. 2 east crosscut, 300 level, is out a total distance of 144 feet; face is in a mixture of clay, porphyry and quartz. West crosscut No. 3, 300 level, has been advanced 35 feet since last report, making its total length 267 feet. The face is in porphyry, clay and small streaks of low-grade quartz. The east crosscut on the 1500 level is out 37 feet; the face is in hard porphyry.

SEG. BELCHER.—On the 600 level the east crosscut from the south lateral drift has been advanced 23 feet since last report, and is now out a total of 331 feet. The face is in soft porphyry.

JUSTICE.—The north drift on the 822 level is still showing quartz that gives low assays.

POTOSI.—East crosscut 400 feet south of shaft, 930 level, continues in a mixture of quartz, clay and porphyry. The bottom of the winze below the 1300 is still in porphyry that shows some quartz. The east crosscut on this level continues to show stringers and feeders of quartz.

CHOLLAR.—Good progress is making in the drift that was recently started 60 feet above the 550 level, at a point 300 feet north of the Sharon shaft. The south drift, 1400 level is still showing streaks of quartz. The east crosscut on this level at the north line continues in porphyry. About the usual amount of ore is being extracted, the average assay of which is a little over \$20 a ton.

ALTA.—The Alta is expected to start up in about 10 days. Supt. Boyle will, in a day or two, inspect the shaft and the height of the water in the mine.

ANDES.—The east crosscut from the south lateral drift on the 420 level has been advanced 18 feet; face in a formation of vein porphyry and clay. Easing timbers in main north drift, 420 level.

OCCIDENTAL.—Extracting ore of fair quality from the stopes on the 400, 600 and 650 levels. A considerable amount of exploration work is being done.

CHALLENGE AND CONFIDENCE.—The joint Confidence and Challenge west crosscut from the north drift on the 300 level is out 62 feet, having been advanced 16 feet this week. The face shows quartz having no value. The joint Yellow Jacket, Confidence and Challenge north drift on 100 level is in 661 feet, 34 feet having been made during the week. The face shows quartz having no value.

UTAH.—The main west drift, still shows material that yields small assays.

CON. IMPERIAL.—We are still following up and taking out small streaks of ore from the upper levels and prospecting in and around the old stopes, where we find some fillings and bunches of ore of fair grade, which is being shipped to the Vivian mill for reduction.

SIERRA NEVADA.—630 level.—From west crosscut No. 1, 155 in, a north lateral drift has been advanced 43 feet. The material passed through being porphyry and clay.

HALE AND NORCROSS.—On the 1100 level of Norcross No. 4 west crosscut near our north boundary was advanced 30 feet; making its total length 170 feet; face in quartz and porphyry. No. 5 east crosscut started on our south boundary was advanced 55 feet; face in porphyry with stringers of quartz. The crosscut is being run jointly with the Chollar Co. At the end of No. 3 east crosscut we are sinking a winze, which is down 20 feet; the bottom shows some good ore. The main incline is now repairing and retimbering 120 feet below the 1400 station. We have men on repairs in the main shaft and during the week we have hoisted from the Savage 548 cars of ore from the 500, 700, 800, 900, 1100 and from the intermediate drifts north and south from the winze below the 1300 level. Shipped to the Mexican mill 528½ tons and milled 424 tons. Average battery assay \$15.60. The bullion yield of the mine for the month of March was \$26,439.16. The upraise from 300 level was advanced 10 feet; total height 147 feet. The top is now in low-grade ore. From the stopes below the 800 and 900 levels we are extracting good ore.

SAVAGE.—We have hoisted 541 cars of ore from the 500, 700, 800, 900 and 1100 levels and from the intermediate drifts north and south from the winze below the 1300 level. Shipped to the Mexican mill 528½ tons and milled 424 tons; average battery, \$15.60. The bullion yield of the mine for the month of March was \$26,439.16. The upraise from the 300 level, has been advanced 10 feet, total height, 147 feet. The top is now in low-grade ore. From the stopes below the 800 and 900 levels we are extracting good ore.

GOULD & CURRY.—200 level: Extracted from old stopes during the week 42 cars of fair quality. Have done some repairing on the 300 and 400 levels in order to keep our air connections open.

BEST & BELCHER.—1000 level: Repaired 20 feet of north drift during the week. 1100—all work in west crosscut No. 1 has been stopped. Northeast drift from east crosscut No. 1 has been extended 25 feet; total 59 feet through porphyry and stringers of quartz showing some value.

Tuscarora District.

NAVAJO.—Times-Review, April 11: Stopes on the 350 level are still looking well. The vein is small but very high grade.

BELLE ISLE.—Drifts from the intermediate crosscut from No. 1 chute, 350-foot level, extended 18 feet. No. 2 chute, same level, extended 7 feet. A

crosscut has been started from the top of No. 2 chute to get at the ore cut by the intermediate crosscut from No. 1 chute.

NEVADA QUEEN.—East crosscut on 650 foot level advanced 13 feet through very hard porphyry. Stopes are producing some high-grade ore.

NORTH COMMONWEALTH.—First level.—Has produced 25 cars first class ore, average car sample \$248 per ton, and 38 cars second class, average \$24 per ton. Second level.—North drift from west crosscut has advanced 20 feet, not looking so well, seams of good ore still in the face. Third level.—West crosscut has been extended 28 feet in porphyry. Fourth level.—East crosscut has been extended 35 feet, water coming through the face.

NORTH BELLE ISLE.—North drift from Belle Isle 450 foot level extended 28 feet, the face continues to show bunches of high-grade ore. No. 1 upraise from the same drift extended 14 feet, the vein in the top is wide and is showing some very rich ore. Resumed work in the east crosscut opposite the vertical winze, 400 foot level, and extended it 17 feet, cutting some good ore. The 300 stopes are producing 12 cars of first class and 112 cars of second class ore. North intermediate drift from No. 4 chute, 600 foot level, extended 10 feet, showing some very fine ore.

COMMONWEALTH.—Fourth level.—West crosscut has been discontinued, and a drift started north on a stratum of ore assaying \$76 per ton. East crosscut has been extended 24 feet in porphyry. North drift extended 13 feet, face showing ore assaying from \$30 to \$86 per ton. Water broke through 10 feet back from the face, started to cave so cannot work, and have started drift in footwall, will take a week to get into the face again. The ore is exposed in the face of drift 2 feet wide, and still showing in the footwall side. It was improving as the drift advanced north. South drift extended 10 feet in the vein, giving low assays, but of no value.

Hot Creek District.

SILVER ORE.—Belmont *Courier*, April 8: J. W. Merritt presented us last Wednesday with two rich specimens of silver ore which was recently extracted from the ledge in the Merritt & Wagner mine, situated in Hot Creek district, Nye county. Specimen No. 1 assays over \$5000 to the ton and specimen No. 2 assays over \$2000 to the ton in silver. Mr. Merritt informs us that the mine is looking well and that the ore extracted from it is shipped to Salt Lake City for reduction.

BRITISH COLUMBIA.

CARIBOO.—New Westminster *Ledger*, April 8: A representative had an interview with Mr. J. Bowron, Gold Commissioner from the district of Cariboo, and also with Mr. W. C. Price, foreman of the Government reduction works at Bikelville. It was learned from Mr. Bowron that a large bed of auriferous gravel has been discovered running parallel with the Canal river and extending for about ten miles, every linear foot of which has produced the value of one dollar. This bed, which was discovered by some Chinamen working close to the forks, lies behind the perpendicular cliffs which here border the river. It is now taken up both above and below the forks, and among the firms working on it are the following: The Victoria Hydraulic Mining Co., the South Walk, Champion, Pomeroy, and Whittier hydraulic mining companies. Mr. Bowron considers this one of the most important finds that has been made for many years. Both gentlemen were warm in their praises of the good work done by the reduction works, under the able superintendence of Mr. E. A. Martin, a gentleman in whom all have the most unbounded confidence, and it is their opinion that these works will do wonders toward developing the quartz mining of the districts, which, on the showing of the Black Jack mine, undoubtedly has a great future before it. But on the other hand both Mr. Bowron and Mr. Price are positive that a railway going by way of Yellow Head pass is an absolute necessity to the thorough development of the country, both in its mining and farming districts.

ARIZONA.

NOTES.—Arizona *Journal-Miner*, April 9: Work on the Ryland mine and mill at Minnehaha will be resumed inside of 30 days. There is some talk that an Eastern company will shortly take hold of the cinahar property in Copper basin. The Dillon brothers are preparing for a shipment of high-grade ore to the sampler here from their rich strike near the Hillside. Placer mining in the foothills east of Skull valley still goes on, over \$200 in dust being received last week from that section. Another batch of rich gold ore was received yesterday at the sampling works from the Bullion-Producer of Messrs. Lang, Blake & Owens. Assayer Hetherington of this city gives a flattering report in mining from the number of orders brought to his office during the past few days for assaying. James Shirley brings the report from the Aztec works on the Hassayampa that the mill is running steadily on custom ore, and that for the present, operations have ceased in the mine. Nick Palmer is running the mill on Jersey tuch on ore from the Storm Cloud, owned by Fred Williams. The results so far shown from the run are satisfactory, and undoubtedly a sale will soon be made. The Crown Point group of mines below Walnut Grove are looking well, and the work of developing them is being actively pushed by Messrs. Brown, Merwin & Brodie. At present there is a force of 25 miners at work on the Congress. On the arrival of Supt. Murphy and the starting of the 40-stamp mill over 100 men are to be put to work. H. L. Jones, who lives a few miles south of town, is the possessor of a claim he recently discovered near his home, which is very rich in gold ore. The work of remodeling the Tiger mine machinery and retimbering the shaft still goes on. A force of 20 men is at present employed under the superintendence of Harvey Helm. It is expected to start the mill crushing inside of 30 days. New timbers have been placed in the Silver Belt, and the work of starting the pumps to clear the shafts of water will begin this week. Work has been resumed in a spirited manner on the Quartz Mountain group of mines, formerly the property of Dan O'Boyle. A Mr. Taylor, representing the Kansas City syndicate, is in charge, and has let several contracts in sinking and drifting, in which a large number of men are at present engaged. There is considerable excitement and bustle in Oak Gulch on the Hassayampa over the recent strike of Mr. Clark on a new claim. The ore vein is about a foot in width and goes over \$300 in free

gold. John Thompson is sinking steadily on the Black Hawk and has many tons on the dump for treatment at the Aztec mill near by. Dan O'Boyle has a force of 10 men on the Lone Pine and Reindeer claims. He intends to run 300 feet farther on these properties and mill the ore at the custom mill. There are 300 tons at present on the dump to treat.

MCCRACKEN.—Mohave *Miner*, April 11: We hear it rumored that the famous McCracken mine near Signal has been sold to Colorado parties for a quarter of a million dollars. The mine is well worth the money and it is worked on mining principles will be one of the largest bullion-producers in the west. The mining outlook in and around Mineral Park is brightening up and the probability is that more men will be worked in the mines here this summer than at any other time during the past 10 years. Wm. Brown is doing considerable work on his gold claim in Weaver district. A new road is being built from his claim to his new arastras and as soon as completed he will commence grinding out bullion.

CUPEL.—A very important strike has been made in the winze in the Cupel, on the Tiger ledge. About eight inches of almost solid ruby ore has been encountered in sinking from the old level. Another contract has been let on the main shaft and it is being pushed as fast as men and muscle can do it. As many men as can be conveniently worked have been put on and as soon as stopping ground is opened the force will be greatly augmented.

COLORADO.

SAN JUAN.—Silverton *Miner*, April 9: The mines of San Juan county that are just emerging from a winter's development never looked better, nor the future more hopeful. The holders of prospects will never see a better demand for claims than there will be this season, and it behooves them to get a move on and show them up to the best advantage. Capital is heading for Silverton.

DAKOTA.

NIGGER HILL TIN.—Deadwood *Pioneer*, April 11: Capt. O. C. Taylor, of St. Paul, who by the way, has been in every tin mining district of note in the world, after thorough investigation, has invested his money and staked his fortune as well as his reputation, on Nigger Hill tin mines. The result is that he now owns 45 claims in a body, with abundance of timber and water for mining and milling purposes. The machinery for a 150 ton concentration plant has been bought and paid for and will be in operation before many months, the boarding house and barn having been completed. Nigger Hill mine owners and those interested in the district are to be congratulated on the fact that a practical test of their ores is to be made.

A GOOD CLEANUP.—Deadwood *Pioneer*, April 10: The Chlorination works' cleanup for the last 15 days of March, was completed yesterday, and gave 570 ounces—\$11,400 pure gold, and \$1500 left in the slag to be reduced. The average product per ton was \$24. The result was satisfactory, and leaves no doubt as to the perfect success of the process. The works will be shut down from Thursday to Monday, pending the laying of the D. C. track to the mine, which will reduce the cost of transportation \$1.50 per ton.

IDAHO.

CARIBOO DISTRICT.—Salt Lake *Tribune*, April 8: Thomas Crane, merchant of Soda Springs, Idaho, is in the city. He gives a hopeful word for the Cariboo district this season. Supt. Erwin of the Nellie Mining Co. arrived from the East last week and went up to Cariboo to start up the 100-stamp mill owned by his company. It is believed that this property will produce much gold this year. Supt. Deliver of the American Placer Mining Co. is expected from the East in a few days to start work as soon as the water begins to run. There will be plenty of water there this season, and they hope to take out more gold than the two last seasons, when there was but little water. A great deal of money has been spent on this property in ditches and flumes.

PROSPEROUS.—Silver *State*, April 8: From B. H. Luther, who just arrived from Idaho, we learn the following: The Del Mar Co. is working 200 men on the White Talk lode. Its receipts for the month of March were \$110,000, and its expenses were \$28,000. The lode is 28 feet wide in places, carrying gold and silver. The town of Del Mar promises to be a good lively camp. The only drawback now is the scarcity of lumber, which has to be hauled nine miles by sledges through snow and several miles by wagon over a very muddy road. Mr. Luther thinks it will be six weeks before lumber can be got into the camp from the railroad. The snow was 10 inches in Del Mar and two feet in Silver City.

FROM SMOKY.—Wood River *Times*, April 10: About a dozen miners who have worked in Smoky are in town. The crust is not sufficiently thick to enable travelers to dispense with the use of Norwegian snowshoes altogether, and the divide will hardly be practicable for horses before the first of May. The King of the West hands have been laid off until about the first day of May, when Charles Reed, manager is expected to outline the summer campaign. There is more than enough ore out to pay all expenses; but it is feared that the discount on silver and the high rates of freight will cause a suspension of operations. The leasers on the Sunday mine have quite a width and depth of ore in sight, and expect to make big money. The heading of the lower tunnel in the Galore-Stormy is in quartz, and the flow of water from the breast does not seem to be any less than for months past. A good body of ore is reported in the Flagstaff mine. Joe Reedy is doing well on the Tyrannus but has nothing big yet. The Silver Star may shut down unless silver takes an upward turn.

MONTANA.

THE KEYSTONE IN ORE.—Helena *Mining Journal*, April 8: The Keystone, in Running Wolf District, and situated near the Mortson & Woodhurst mine, is said to have recently developed a fine showing of ore. The owners, Packard, Frazier & Woodhurst have followed the ore on an incline to a depth of 80 feet. At the surface, the vein was only one foot thick. This pinched until the ore streak was only two inches wide and continued about the same

for nearly 20 feet. It then commenced to widen and is now over five feet thick and all ore. The vein contains several kinds of ore, the principal being hard carbonate, running well up in silver, galena, chloride of silver and soft carbonate. Fifty tons of shipping ore have already accumulated on the dump which is growing perceptibly larger with each day's work. Mining men who have examined the property unite in the opinion that it will prove one of the bonanzas of the district.

STRIKE IN THE EXEMPTION.—A strike was made Monday on the 60-foot level of the Exemption, in Horse Canyon, near Butte. The chute is fully three feet wide and the ore will run fully 25 per cent copper and some silver. The vein is well defined and lies between tide walls. Considerable water came in with the ore.

OUTLOOK.—Montana *Review*, April 11: The mining outlook, so far as the precious metals are concerned, is very gratifying to all who are interested in mining in Montana. The erection of a smelter at Castle by the Cumberland Co. has given that camp an increased interest which nothing but the starting of a railroad for that point could exceed. Neihart and Barker are coming to the front in fine shape, and it looks as if Cooke City would make some advancement in spite of the fact that no railroad is probable this year. Around Helena there is much interest excited, and we are much mistaken if some of the gold properties in Oro Fino and Tucker gulches, within three or four miles of Helena, will not be largely worked before summer has come. Rimini mines will be worked to a larger extent this year than last, and the mines around Marysville will make a good showing also. The mines of Jefferson Co., contiguous to Helena, will turn out more ore than ever before, and more new prospects will be worked this year than in any previous one. Copper properties may not be profitable in the near future, but better times will create more demand for that metal, and before the year closes we expect to see copper bringing its old prices.

NEW MEXICO.

LITTLE GIANT.—Pinos Altos, April 10: Wm. Baxter is engaged in pumping the water from the Little Giant mine, with the object of keeping it below the first level, 143 feet. The Little Giant will be started up again in the near future. The gentlemen interested in this mine realize they have a good thing and intend to utilize it. The shaft of the Ohio will be sunk 30 feet more and then drifts will be run both north and south. The north drift will connect with a tunnel already in some distance. Charles Murton and Harry McCool have contracted to sink a 100-foot winze 456 feet on Aztec vein in the Kleptomania shaft. This winze is to connect the 250-foot with the 350-foot level. Robert Kirk and A. S. McDonald are the owners of the claim adjoining the Dimnick strike on the north. This claim is on the same lead and promises to rival its southern neighbor in the quality of its ore.

OREGON.

MYRTLE CREEK MINES.—Cor. *Oregonian*, April 10: The chief product of our mines has been gold, and the placer mines of Southern Oregon have always taken the lead. Nor is the gold of this region exhausted yet, by any means. Millions of dollars' worth of gold only await the appearance of some mining genius to discover a practicable and profitable method of obtaining it. The great drawback is the scarcity of water. There are large areas of these lands where water cannot be obtained at all. The Myrtle creek mines have been known for years and much gold has been taken from them, although the miners were compelled to work them by the use of what little water they could obtain by catching it in ditches dug on the side of the mountain and amounting only to the slight fall of their rainy season, usually lasting only a few weeks of the year. The character of the soil is very similar to that of the best gold-bearing regions of California—a red soil filled with small quartz, small nuggets of iron ore, black sand and bearing gold. One peculiarity of these mines is the absence of large stone. Almost every particle of the dirt can be passed through the sluice box. A more perfect mining field could hardly be imagined than these mines possess. They are situated on the side of a mountain which rises more than 600 feet high, and at its base flows the beautiful stream called Myrtle creek. Every foot of the mine can be worked. Recently some expert miners visited these mines, and on finding them to prospect exceedingly well and finding how much gold had already been taken from them, they set about to discover some method of overcoming the only obstacle that had so long prevented these mines from being worked—the scarcity of water. Their engineer discovered that they could, by digging a ditch 10 miles long, bring to the very top of the mountain, and extending the entire length of the mine, a stream of water sufficient to run two giants day and night during the rainy season. A stock company was organized and the mines (over 1400 acres) immediately purchased. The ditch has since been dug and the company is already operating a hydraulic. This stream will furnish water to run two giants during the rainy season only; but by digging a ditch 17 miles farther they can procure all the water that they can use the year round, and before the end of the year the company expects to have the remainder of the ditch in operation. The writer recently visited these mines and found that they prospect exceedingly well. Gold can be found in almost any pan of dirt taken up promiscuously anywhere on the mines. There is no flake or very fine gold, but it is in the form of small nuggets. Some of the prospects are exceedingly rich. The first cleanup will take place in less than a month, but the company will start a force of men to work on a short ditch this week, which will give them water the year round. They will take the water from Myrtle creek, which is probably the richest part of the mines. This ditch will be completed by the time the water falls in the other ditch on top of the mountain, and thus they will work the mine the year round. It will be a great boom for Oregon when the mines of Southern Oregon are thoroughly developed and the water question shall have been solved.

UTAH.

GILSON'S DUGWAY SAMPLES.—Salt Lake *Tribune*, April 8: The Union Assay office yesterday

made an analysis of two lots of ore brought in by S. H. Gilson from his Buckhorn mine, Dugway district. This ore has been exciting much interest the past few days, and it places Dugway above being entirely a low grade camp. There were two lots of ore, one being first-class and the other second, and the result is shown as follows: First-class, 9534 pounds ore, 9.7 per cent lead, 602 ounces silver, and 4.8-10 ounces gold. The analysis showed silica 37.4; iron 6.4; and zinc 9.9 per cent. The second-class ore, 7040 pounds, went 1 per cent lead, 136.5 ounces silver and about 1 ounce gold; silver, 24.7; iron, 1; zinc 2.4, and lime, 19.1 per cent. Such ore ought to make Dugway a big camp, providing there is much like this, and it is understood that the deposits are very great there. Already the news of this rich find by Mr. Gilson and some others has started prospectors toward the Deep Creek country, and it now looks as if there will be quite a stampede for that new Eldorado.

SAMPSON SHIPMENT.—James Johnston was paid yesterday for 110 tons of ore from the Sampson mine, Bingham. This ore assayed 54.3 per cent lead and six ounces silver, and sold for \$27.81 per ton. The Sampson is on the same vein as the Yosemite No. 2, and is giving promise of becoming a great property. It certainly has done well since ore was struck on January 2d last. Since then 440 tons of ore have been shipped and sold, and now 100 tons more is ready to forward to the smelters as soon as the roads are so it can be hauled to the railroad to ship. The mine is opening out larger and better as drifting on the vein is carried forward.

BUNKER HILL ORE.—J. C. Reynolds of Stockton is in with thirty tons of ore from his Bunker Hill mine, which will run about 20 ounces silver and 55 per cent lead. This property is opening out nicely. It has a shaft down 80 feet, and in drifting the face has three and one-half feet of ore.

OPHIR.—Salt Lake *Tribune*, April 2: Good news comes from the Trace and Banner property on the north side of Lion Hill, Ophir. H. E. Wylie of Ophir owns one half of it, and the other half belongs to Judges Bennett and Harkness of this city. Mr. Wylie has persistently stayed by the camp for several years and pushed work on the tunnel, which is now in 800 feet, and has reached a depth of 300 feet beneath the surface. About ten days ago the tunnel tapped a very rich body of ore, on which they have been drifting since, and it is now four feet wide. It is not only rich in silver, but carries a good amount of gold. This is free milling ore and promises to become the best strike ever made in Ophir district.

CENTENNIAL-EUREKA ORE SALES.—The Centennial-Eureka Co. sold twenty-four tons of ore yesterday to the Hanauer smelter. This was not of their higher grade, and yet it brought \$3,147.69, while the assays ran 7.4 per cent lead, 156.55 ounces silver and .465 of an ounce in gold.

HORN SILVER ORE SALES.—The Horn Silver Co. sold three lots of ore yesterday, aggregating 756 tons net. Of this Conklin got 330 tons for the Pueblo works, Scott & Anderson took 110 tons to send to the Aurora (Illinois) smelters, and the Germania Lead Works got 310 tons for treatment at their works below this city.

WASHINGTON.

RUBY HILL DISTRICT.—Spokane *Chronicle*, April 8: Mr. S. Lichtenstadter, a prominent mining man and banker of Ruby City, and widely known among miners, arrived yesterday in Spokane. On being asked the news from Ruby City, he said: There are comparatively few, if any, mines in operation now. The owners of the Fourth of July mine are getting ready to begin business and will employ about 40 men. Mr. Duval is now in the East negotiating for a mill to be put up at this mine. The Ivanhoe people have already gone to work with a full force of men. The mine has about \$150,000 worth of ore in sight. Mr. Cawder, one of the owners, is in Portland getting machinery for it. The Ruby Hill M. Co. has started work and has enough capital to keep going with a full force all summer. The work will mostly be developing the mine. The First Thought is working a full force of about 50 men. They are making regular weekly shipments both to Helena and to Butte. Rumor has it that this mine has been sold to a San Francisco syndicate, which Mackay controls. What lends color to this rumor is that its owner, Jonathan Bower, is in San Francisco on business connected with that mine. If that is true it will be a big thing for that district, for we need men of his energy and capital to make things lively there, and if Mackay is in it he will do that very thing. The La Una, in Mineral Hill, is going to start soon. Thomas Mason, of Tacoma, is the owner. Mr. Gil Chelson is preparing to ship a carload of high-grade ore out of the Silver Belt, to Butte. In Concomully, better known as Mineral Hill, they are doing very little now. The reason is that Mr. Allen Mason, who is heavily interested there has been away on a European trip. He has just returned and the Lone Star mine will at once start up with a full force of men. There is also some talk of the Lady of the Lake mine being worked this year. The Black Bear and War Eagle are two gold properties on Palmer mountain. A fine stamp mill is being built there and it will begin producing in 90 days. You see ours are large quartz ledges and the ore has to be reduced either by the milling or the lavation process. An immense amount of capital is necessary for the development of such ledges and also a continuous outlay for several years without any returns whatever. In this respect it differs much from the Cœur d'Alene mines where a man with small capital can work with some success. Another item of news is that we are going to build a flume four miles long from Salmon creek. This will give us a fall of 300 feet and 1000 horse-power. Power will thus be furnished for electric light and cars and also for running a tunnel into Ruby hill 300 feet long, the object being to strike the ledge 1850 feet underground. This will be completed in a year and then we will have greater depths to our mines than they have in Butte. The ledges are from 60 to 80 feet wide and the output practically unlimited. We must, however, have better communication than at present. Salt is a great factor in the reduction of our ores, and freight rates are now so heavy that they would eat up all the profits. But this difficulty will be soon remedied to a certain extent. The Canadian Pacific is building down to the Okanogan lakes at present, and they intend to run boats down to within 50 miles of the boundary line.

MECHANICAL PROGRESS

Electric Iron.

In July, 1880, Mr. James Barnett of Kentish Town, England, sent the following communication to *London Iron*. It was accompanied with an engraving, which we do not reproduce:

TO THE EDITOR OF *IRON*.—"There is nothing new under the sun," so it has been said. Meteoric—or electric iron—is not new, but what has been hitherto only seen of it has been made in the laboratory of the skies, dropping down to us from the rift clouds when thunder-stricken. In meteoric iron we are presented with the nearest approach to perfection in that metal which we can well imagine it to be capable of reaching. We are, moreover, shown therein something of what such a metal—the most useful and most abundant—can be made to do for us, provided that something like Nature's mode of producing the quality she can make be followed by man. The height of human endeavor has for its aim, if well directed, the limitation of Nature's processes, and success is in exact proportion to the nearness of approach accomplished by us in the direction of Nature's work. Simply stated, such samples of meteoric iron as have "come down" to us, present samples of what can be produced when electric action is employed.

In the production of iron, that material which is more largely than any other used in those industrial occupations upon which the mass depends for support and society for its advancement in material wealth, it must be of the highest consequence to adapt to its manufacture that "force," the volume of which is just beginning to be an open book, and the pictures in which are much plainer to the eye than the explanation of them are intelligent to the ear. Providing that electricity can be utilized by being brought within conditions sufficiently economical, and that those conditions can be made to apply upon a commensurately large scale, given these, and then the increase in the production of an invaluable metal becomes illimitable. The illustration given represents a sample of pig iron which has been subjected to electrical action.

My object in alluding to this particular specimen has been to prove the *bona fides* of the experiment, which is distinctly an instance of the practicability of producing electric iron, for here I show a piece of pig in the actual course of undergoing electrical action. I purposely arrested the process at a moment sufficiently early to preserve a dual condition of the metal acted upon. It is unmistakably a piece of pig, and upon the surface it is shown to be in the transitional stage of passing from common pig iron into a metal more highly refined than any that has ever before been seen, excepting when in the meteoric state.

The engraving as given in the paper from which we have quoted was made from a photograph and gives in quite full relief numerous ridges as of fibrous iron, giving the specimen an appearance of being in the act of being converted from an ordinary piece of cast iron into that of strongly marked fibrous iron. The sample, without explanation, would be a perfect riddle to any metallurgist. The paper above quoted concludes as follows:

It challenges attention toward the solution of one of the most important questions of the day. It defies dispute as to the fact of electrical agency having been successfully applied, and therefore makes its practicability a foregone conclusion. As to the question of its costliness, I may dispose of that satisfactorily by saying that, when the manufacture of electric iron is ready to be proceeded with upon a scale commensurate with the demand there will be for it, no iron besides will be able to compete with it for price.

We are not informed as to the manner in which the specimen was subjected to the action of electricity, but have introduced the article in this place merely as a prelude to the following process, which, perhaps may be considered a practical development of a process first suggested, as above, over ten years ago. We copy now from a late number of the *Electrical Review*:

Electrolytic Production of Pure Iron.

A process for the direct conversion of pig iron into wrought or ductile iron, without decarbonization by heat, has been invented and worked out into practical shape by Dr. Stephen H. Emmens, of Emmens, Pa., the inventor of the powerful explosive which bears his name, and is now most successfully going through the ordeal of government tests. Wrought iron, so called, is to-day most universally produced by the process of puddling cast or pig iron, the higher and costlier grades of pig being used, especially in the production of the finer brands, known as "Norway" and "Swedish" iron. The puddling process may be said to be simply the burning out of the contained carbon by the agency of heat and oxygen, and successful puddling requires great skill and extremely hard labor, which must be paid for accordingly. The Emmens process, as to the actual conversion, requires no heat and no skilled labor; but for

merchandiseable bar or sheet iron, the product is simply heated and rolled or hammered. The process is hardly to be described as decarbonization of pig iron. To coin a word for the purpose, "defecation" of pig metal would more accurately describe what takes place. The process is electrical and the pure iron is extracted from the crudest and most impure pig iron or pot metal with as much facility as from the best charcoal pig.

Many attempts have been made to force iron into the list of electrolyzable metals, but failure has marked all efforts except in the electroplating of engravings or copper electrotypes with a coating of hard iron. The difficulty has been completely overcome by Dr. Emmens, whose electrolyte and current treatment are such as to form a perfectly reguline and closely adherent cathode of iron of almost chemical purity, which then only needs washing, heating and rolling to produce an article equal to the finest Swedish iron, being very soft and easily worked. The inventor claims to be able to make the iron from pig, and put it into merchantable shape at a less cost than the ordinary puddling process, and at the same time to further cheapen the cost by using the very lowest priced grades of pig iron. If this be true, and there seems to be no reason why it is not, the effect can hardly be safely predicted. Electricity as a commodity is now a very cheap article, and its production is as certain and uniform as the laws of science can make it. It is said that the residue of the anode, composed of graphite, silicon, sulphur, phosphorus, etc., from which the iron is, of course, absolutely freed, makes a valuable basis for mineral paint, and probably this is the case.

The metallurgist will at once realize the value of this process, if for no other reason than that it at once makes available, for the production of iron, immense deposits of iron ore in various parts of the country which are now useless, owing to the prohibitive quantities of phosphorus and sulphur they contain. Such ores are not available even for the Bessemer or open hearth process, which produces low steels containing a very small proportion of carbon. But for the Emmens process these ores are practically as good as any. They can be melted, run into slabs of proper size and shape, and the only effect of the impurities is upon the character of the anode residue. The cathode will in all cases be practically and almost chemically pure iron. Not only that, but when heated and rolled or hammered, its quality is of the very highest grade. If, as seems to be fairly within the truth, such iron can be produced from such pig at a cost below or even the same cost as an equal quality by the puddling and refining processes, the result must be necessarily important in the future development of the iron industry.

The process is of interest also to the electrical fraternity in point of utility. The forged product is said to be surpassing in its fitness for magnet cores for all purposes, on account of its great purity and the low resistance of a magnetic circuit composed of it. This would seem to be true by comparison. The most impure cast iron has the least magnetic permeability, and the coefficient of the latter rises as the cast iron approaches the character of wrought iron. Swedish iron is the purest commercial iron we are acquainted with, and we all know its splendid magnetic-making properties when energized. The Emmens' iron, being still purer, ought to make a proportionately better electro-magnet. If it does, the electrical industries alone will create a heavy demand for the new product.

STEEL STAY BOLTS.—Steel, as a material for boiler stay bolts, is not meeting with the qualified success that has allowed the introduction of the same metal for the plates of the boilers themselves. More than one large railroad company has abandoned its use after an impartial trial, and returned to sligo, or some equally good brand of iron. The objection to the employment of steel is the great number of stays which break off, after a service of only a few months. In one boiler we examined recently, there were no less than 250 odd steel stay bolts broken, mostly in the throat sheet, and the front parts of the side sheets, after being in use nine months. The reason of this short life is undoubtedly the crystalline structure of steel, and the repeated bendings to which the stays are subjected, owing to the difference in expansion between the inner and the outer fire box sheets that they brace together. Several expedients have been tried with a view to obviating the destructive bending stresses, such as ball and socket joints for the stay bolt heads, etc., but nothing has yet been found to answer all the requirements. It is therefore safe to assume that as long as flat surfaces, stayed transversely by bolts, are employed in boiler work, just so long will there be trouble experienced with breakages—in other words, the evil is inherent.—*Progressive Age*.

COMPILMENTARY.—Sir James Kilsen's address in replying to the address of welcome given to European guests of the American Institute of mining engineers at the time of their recent reception at Pittsburgh closed with the earnest expression of his belief that the United States and England were necessary to each other in the interchange of products and brains, and he was convinced that "through such orderings Providence has designed to wind the silken chain of commerce round the world."

SCIENTIFIC PROGRESS.

Water and Temperature.

The changes in the temperature of water afford a very interesting study. In the form of ice the temperature may be 32° F., or lower, according to the temperature of the surroundings. Although the freezing temperature of pure water is 32° F., yet by observing certain precautions the temperature of the water may be reduced several degrees below this before congelation will take place; but in the act of freezing a certain number of units of heat are given out, due to the amount of work done in changing the form of the water. One pound of ice has a greater bulk than the one pound of water from which it was formed, because water is at its greatest density at a temperature of several degrees above the temperature of solidification. One pound of water in changing into ice will develop 140 heat units, and each unit of heat is equal to 772 foot pounds, it is evident that the freezing of one pound of water will develop a force equal to 108,080 foot pounds.

If the freezing was accomplished in one minute of time, an amount of energy equal to 3.27-horse power would be transformed. While the water is freezing this heat is given out, but that does not reduce the power required to bring about the change, for the heat has to be removed. But the removal of this amount of heat does not lower the temperature one degree, for although the water has been changed into ice, it still has the temperature of 32°. After the ice is formed, its temperature may be reduced to that of the surrounding air.

In changing ice into water, the same amount of heat is absorbed by the water as was given out during the freezing process, and the same amount of power in the form of heat will be required to produce the change; and although the ice is melted over a strong fire, the temperature of the water will not be raised above 32° until all the ice is melted, providing the water has a chance to circulate freely.

In water there appears a departure from the law of expansion and contraction, for in the case of water at a temperature of 39°, at which the water is at its greatest density, a change of temperature either above or below this will cause an expansion of the mass. As the temperature decreases from this point, it expands in nearly a regular manner, so long as the temperature continues to decrease. If heat is motion and produces motion in the atoms, and this motion causes expansion, then why is it that the abstraction of heat from ice causes the same phenomenon that in all other substances is the result of an increase of temperature. I know of no way to explain it, but it is a subject that has received a great deal of attention.—*Stationary Engineer*.

A Fly on the Wing.

There are many insects which one would little suspect to be furnished with apparatus suited to swift and more or less continuous flight. House-flies frequent the inside of our windows, buzzing sluggishly in and out of the room. But what different creatures are they when they accompany your horse on a hot summer's day. A swarm of these little pests keep pertinaciously on wing about the horse's ears; quicken the pace up to ten or twelve miles an hour, still they are there; let a gust of wind arise and carry them backward and behind, the breeze having dropped, their speed is redoubled, and they return to their post of annoyance to the poor horse even when urged to its fastest pace, says the *New York Ledger*.

But this example gives only a partial proof of the fly's power of flight, as the following will show: The writer was traveling one day in autumn by rail at about twenty-five miles an hour, when a company of flies put in appearance at the car-window. They never settled, but easily kept pace with the train; so much so, indeed, that their flight seemed to be almost mechanical, and a thought struck the writer that they had probably been drawn into a sort of vortex, whereby they were carried onward with but little exertion on the part of themselves. But this was soon disproved. They sailed forth at right angles from the train, flew to a distance of thirty or forty feet, still keeping pace, and then returned with increased speed and buoyancy to the window.

To account for this, look at the wings of a fly. Each is composed of an upper and lower membrane, between which the blood-vessels and respiratory organs ramify so as to form a delicate network for the extended wings. These are used with great quickness, and probably 600 strokes are made per second. This would carry the fly about twenty-five feet, but a sevenfold velocity can easily be attained, making 125 feet per second, so that under certain circumstances it can outstrip a race-horse. If a small insect like a fly can outstrip a race-horse, an insect as large as a horse would travel very much faster than a cannon-ball.

LIFE OF LICHENS DURING WINTER.—Of all plants, lichens are the ones that most easily endure the lowest temperatures. They are met with in profusion in the polar regions and at the highest altitudes, where no other plant can subsist. The causes of this peculiar resistance being unknown, Mr. H. Jumelle decided to ascertain how, from the standpoint

of gaseous exchanges with the atmosphere, the lichens of our country behave during the winter. The study of this point was evidently capable of throwing light upon the question of the resistance of these plants. The results obtained by Mr. Jumelle and recently communicated to the Society of Biology, are as follows:

In our country, when the temperature descends below zero, lichens enter upon a retarded course of life due less to the lowering of the temperature than to a loss of water. In lichens that grow under shelter and on the ground, the loss of water being less, the gaseous exchanges will be merely decreased, and remain sensible. On the contrary, in lichens living upon trees and exposed to the air, desiccation occurs to a considerable extent, and life is then so retarded that, in darkness as well as light, the gaseous exchange no longer becomes appreciable. If, by chance, the lichen contains a notable proportion of water, the freezing of the latter produces an effect analogous to that of desiccation, and the gaseous exchanges are again of the feeblest character.—*Revue Scientifique*.

The Eyes of Deep-Sea Fish.

The queerest thing about deep-sea creatures is their arrangements for vision. Fish that live at very great depths have either no eyes at all or enormously big ones. Indeed, there are two ways you may get on in these gloomy abysses, by delicate touch organs, or by sight that collects the few rays of light due to phosphorescence or other accidental sources. Now, as we go down in the water we find at each depth that the effects produced upon the eyes of fish are steadily progressive in one direction or the other. Species that live at a depth of eighty fathoms have the eye already a good deal bigger than their nearest representatives that live at or near the surface. Down to the depth of 200 fathoms, the eyes get constantly bigger and bigger. Beyond that depth small-eyed forms set in, with long feelers developed to supplement the eyes. Sight, in fact, is here beginning to atrophy. In the greatest abysses the fish are mostly blind, feeling their way about entirely, by their sensitive bodies alone, over the naked surface of rock at the bottom. Some of them have still external relics of functionless eyes; in others, the oldest and most confirmed ahyalal species, the eye has altogether disappeared externally, though its last representative may still be recognized imbedded deep in the tissues of the head.

But many deep-sea fishes have a curious system of hollows in the skull, or along a line on the body, which secrete mucous or slime, and this slime often envelopes them completely, as in a sheet of jelly, from head to tail. Strange to say, it is phosphorescent. Moreover, many other deep-sea species have two sets of organs buried in their skin, consisting of round, shining, opalescent bodies, very closely resembling mother-of-pearl. One sort is large and oval and is placed on the head not far from the eye; the other kind is smaller and arranged in a series along the body and tail, a pair usually answering to each joint of the backbone. All of them are abundantly supplied with nerves, and they seem to be organs for the production and perhaps also for the perception of phosphorescent light. If so, we may suppose that each such fish goes about like a string of glow worms, or a train of lighted cars, all the organs along his side or tail shining faintly in the dark, somewhat after the fashion of luminous paint. Dr. Gunther suggests that in certain cases the phosphorescence may be produced in a sort of back chamber of the organ, and then emitted in particular directions through the lens in front, precisely as a policeman flashes his hall's eye on any suspected point.—*The Cornhill Magazine*.

THE EARTH'S AXIS.—Two weeks ago we gave an item in this column in regard to a recently observed variation in the earth's axis, which was attracting much interest among scientists in Europe. Since that time we notice that a movement has been set on foot in this country to investigate this phenomenon under the auspices of the International Geodetic Association. Observers in general have been requested to make simultaneous observations during a given space of time, and, in addition, eminent scientists will make observations in different parts of the world. Mr. Preston, on behalf of the United States Coast and Geodetic Survey, will establish a station on the Hawaiian Islands; Prof. Marcuse, on behalf of the European scientists, will occupy a station on one of the South Pacific Islands, and Prof. Deviden will conduct his observations at the Astronomical and Longitudinal Station in Lafayette Park in San Francisco.

PHOTOGRAPHING UNDER WATER.—Mr. Masey has succeeded in photographing the movements of fishes under water, taking proofs at the rate of 50 a second with exposures from 1-2000 to 1-3000 of a second. A set of 12 photographs gives all the phases of the undulations which the medusa impresses upon its umbrella of a locomotor apparatus. Another series exhibits a squid leaping out of the water. A rag has also been taken in profile while waving the edge of its flat body, and the curious mode of progress of a comatula has been taken.

THE CON. CALIFORNIA AND VIRGINIA MINING CO. is not affected much by the discount on silver. More than half of the bullion product last month was gold.

ELECTRICITY.

"The Storage Battery."

Electricity, like water, depends for its power of doing work on two conditions: quantity and force; its potentiality increases according to the place where it is produced as compared with that at some other place. The difference of potential corresponds with the difference of pressure in gases, with the difference of temperature in heat. As the sea level is the standard for measuring the height of a mountain, so are electric levels measured from the arbitrary level of the potential of the earth.

A storage battery does not store electricity any more than the spring of a clock can be said to store time or sound; it stores energy. The energy of an electric current is used to produce a decomposition of metal of such a nature as will of itself produce a current on the removal of the original current. The accumulators are two plates of metals immersed in a liquid acid which is called the electrolyte, and which cannot act on the plates except while an electric current is passed through it, which effects its decomposition in depositing its positive and negative constituents on the two plates. On the cessation of the current the cells are discharged by a connection outside the liquid, in the opposite direction. Plates of compressed litharge have been recently used, and many experiments are being made in the hope of obtaining such results as will avoid the necessity of using a dynamo. Electric meters are those in which a portion of the current passes through a solution of a metallic salt, and the strength is determined by the amount of electrolytic decomposition it effects. There is also an electro-thermal meter to measure the heat caused by a certain resistance, or by the amount of a liquid evaporated by the heat generated by the current; and an electromagnetic meter, in which the current is measured by the magnetic effect. It proceeds upon a needle by deflecting it.—*Exchange.*

ELASTIC ACCUMULATORS.—A novel form of accumulator has just been produced by M. Emile Reynier. This battery affords in a simple compact structure a high voltage, and at the same time improved modifications for securing additional solidity and transportability. The essential advantage of this battery consists in its possessing a certain amount of elasticity from its peculiar construction. It has sixteen plates mounted in flexible pockets, and these elements are placed flat, one against the other, and compressed between two end plates of wood by means of rubber spring bands. This spring arrangement gives to the active solid matter an artificial elasticity which results in large specific power and storing capacity. This is only one of the many important improvements which have recently been effected in the storage battery, and which are gradually bringing that mode of generating electricity to a stage of perfection which will lead to its general adoption for propulsive and other purposes.

ELECTRIC WIRES ON ROOFTOPS.—United States Circuit Judge Sawyer has decided that the municipal ordinance prohibiting the placing and maintaining of electric wires on the roofs of buildings is valid and constitutional law. Soon after the ordinance was passed, Chief Engineer Scannell of the Fire Department began to cut down some of the wires of the Electric Improvement Co. The company filed two actions in the Circuit Court against the City and County of San Francisco and Chief Scannell. The company wanted to restrain and enjoin the Board of Supervisors and the Chief Engineer from carrying out the provisions of the ordinance. Judge Sawyer decided that the supervisors have a right to pass laws for the protection of public interests and the safety of the community, even when private interests are injured. The injunction was dissolved. The decision was rendered in the action against the city, but the same applies to the case of Chief Scannell.

THE UTILITY OF THE ELECTRIC LOCK.—Dwellings and buildings of all kinds are now rendered secure with greater facility than ever by means of the electric lock. By the use of this lock, which can at any time replace the lock ordinarily used, the entrance doors of private residences, apartment houses, offices, banks, etc., can be absolutely controlled by a person in another part of the building. The pressure of a button located at any desired point, closes the circuit, and the current passing through the magnet inside the lock, releases a lever. The spring then throws back the bolt, and the opposite knob can be turned and the door opened. In apartment houses the button (one for each suite) is placed near the speaking tube, which runs to the outside door.

SIGNING A CHECK BY ELECTRICITY.—One of the marvels of electricity, and one of the most striking of the Edison exhibits at the Paris Exposition, was the little instrument which enables the operator to sign a check 100 miles distant. The writing to be transmitted is impressed on soft paper with an ordinary stylus. This is mounted on a cylinder, which, as it revolves, "makes and breaks" the electric current by means of the varying indentations on the paper. At the receiving end of the wire a similar cylinder, moving in accurate synchron-

ism with the other, receives the current on a chemically prepared paper, on which it transcribes the signatures in black letters on a white ground.

ELECTRICAL WORK IN FRANCE.—Various new applications of electricity are reported from France. It is said that the government military workshops at Mendon are now quite busy with the manufacture of electric motors for the use in ballooning in time of war.

THE BUILDER.

ARCHITECTURE IN CALIFORNIA.—The American, says a correspondent of *Harper's Magazine* have not the art of making houses or a land picturesque. The traveller is enthusiastic about the exquisite drives through these groves of fruit, with the ash or the snow-covered hills for background and contrast, and he exclaims at the pretty cottages, vine and rose clad, in the semi-tropical setting, but if by chance he comes upon an old adobe or Mexican ranch house in the country, he has emotions of a different sort. There is little left of the old Spanish occupation but the remains of it to make the romance of the country, and appeal to our sense of fitness and beauty. It is to be hoped that all such historical associations will be preserved, for they give to the traveller that which our country generally lacks, and which is so largely the attraction of Italy and Spain. Instead of adapting and modifying the houses and homes that the climate suggests, the new American comes here brought here from the East the smartness and prettiness of our modern nondescript architecture. The low house, with recesses and galleries, built round an inner court, or patio, which, however small, would fill the whole interior with sunshine and the scent of flowers is the sort of dwelling that would suit the climate and the habit of life here. But the present occupiers have taken no hint from the natives. In village and country they have done all they can, in spite of the mesquite and the cactus and the palm and the umbrella tree and the live oak and the riotous flowers and the thousand novel forms of vegetation, to give everything a prosaic look. But why should the tourist find fault with this? The American likes it, and he would not like the picturesqueness of the Spanish or the Latin races.

SAFE ROOF BUILDING.—Vice-President Atkinson of the Boston Manufacturers' Mutual Insurance Company, in an address recently delivered before the Architectural Club of Boston, made some pertinent suggestions concerning the construction of roofs, in effect as follows: The true principle is—first, to understand what purpose is desired in the building proposed, and to build to that purpose. He would reverse the ordinary methods of building, and would plan the roof first. The purpose of the roof is not merely to keep out the rain, but it should also keep out weather changes; keep off fire, etc. The ordinary roof meets none of these points. The modern roof, such as the great fire in Boston, was described as a structure of light wood and felt, covered with slate. The slate cracks easily under either heat or cold, admitting rain, attracting heat and inviting conflagration. He said then some of the very best roofs are over the oldest factories, with solid frames, matched boards, covered with lime mortar, upon which the shingles were laid. There were no shingles laid on boards to decay quickly and kindle readily. His ideal roof would be nearly flat—an entirely flat roof will shed rain. That it will collect snow is not a criticism, for a roof should be as strong as the floors. Under any circumstances not over a foot of solid ice could accumulate, and any decent roof could bear that. Roofs of the barn style, mansard, etc., are denounced by underwriters as inviting destruction by fire. He would have no hollow cornices, for the same reason. The best way is to pitch the roof of industrial buildings toward the center, with only a pitch of half an inch to a foot. This carries the water away through a channel not exposed to frost, and admits of much better advantages of light in the upper story. The use of parapets was commended as especially desirable. He gave as the average cost of a factory building 75 cents per square foot of flooring, in buildings of two or more stories in height. For some reason a flat roof is objected to in a country house, but when the use of the house is considered, the advantage of the flat roof will appear.

BLOCKS OF COMPRESSED WOOD AS A SUBSTITUTE FOR BRICKS.—If we may believe German journals, brick and terra-cotta are no longer to stand alone as the best fire-resisting building materials. A new hotel, which has just been put up at Hamburg, is described as being built entirely of blocks of compressed wood as hard as iron, and by subjection to certain chemical processes rendered absolutely proof against both fire and the attacks of insects. If the claims of the inventor are well founded, he is clearly wasting time in the Fatherland, and should come over to us with his invention without delay and reap the reward of his labors. A process for making wood fire proof is just one of those things which American builders have been banking after for some decades past.

SOMEBODY has said that railroad companies seem to have the power of hypnotizing Legislatures by simply making passes.

GOOD HEALTH.

TO RELIEVE AN OVERWORKED BRAIN.—A Swiss doctor says that many persons who extend their mental work well into the night, who during the evening follow attentively the program of a theater or concert, or who engage evenings in the proceedings of societies or clubs, are awaked in the morning or in the night with headache (the *Sanitary Inspector*). He is particular to say that he does not refer to that headache which our Teutonic brethren designate *Katzenjammer*, that follows certain convivial indulgences. This headache affects many persons who are quite well otherwise, and is due in part to the previous excessive work of the brain, whereby an abnormal flow of blood to that organ is caused; in part to other causes, for example, too great heat of rooms, contamination of the air with carbonic acid, exhalations from human bodies, and tobacco smoke. For a long while the doctor was himself a sufferer from headache of this kind, but of late years has wholly protected himself from it by simple means. When he is obliged to continue his brain work into the evening, or to be out late nights in rooms not well ventilated, instead of going directly to bed, he takes a brisk walk for half an hour or an hour. While taking this tramp, he stops now and then and practices lung gymnastics by breathing in and out deeply a few times. When he then goes to bed, he sleeps soundly. Notwithstanding the shortening of the hours of sleep, he awakes with no trace of headache. There exists a clear and well-known physiological reason why this treatment should be effective.

THE REAL CAUSE OF DEATH.—The most common cause of death is fat and lime. Microbes are mere accessories in causing death. Take myself as a case in point. Once, when younger, I could lift my leg on a level with my head, writes a doctor in the *St. Louis Globe-Democrat*. It is an effort for me now to get it half that distance. Lime deposits are the cause of it. It is only a few days since that I performed a post-mortem on the remains of a distinguished journalist who died in this city at an advanced age. When I reached his heart I took my knife and on rubbing it over that organ it sounded as if it were being rubbed over a rough stone. The heart was fairly encased in lime. I have now under my care a distinguished literary man—a nonagenarian. He is going to die. (The patient has since died.) His death will be caused by abnormal deposits of lime. There is no mystery in death. It is as natural for man to die as to be born. We are born, we develop, we grow ("grow" is right) and we die. Is there anything strange about that? Man is like a tree. He lives his time, then withers, decays, dies. When we shall have learned everything we shall be wise enough to prolong the life of man, but by reason of the materials of which the body is composed he must die.

CANCER AND SMOKING.—Since the death of President Grant, a constant smoker, cancer of the tongue and cigar smoking have been closely associated in the public mind. Surgeons of experience find that the disease is far more frequent in persons who have been in the habit of smoking. The disease appears to be about six times more common in males than in females. The affection known as "smoker's patch" is common. It is a slightly raised oval area on the forepart of the tongue, a little to one side of the middle line, just where the end of the pipe rests, or where the stream of smoke from the pipe or cigar impinges on the surface of the tongue. The patch is usually red, but it may be bluish or pearly white. It lasts for years, but tends to spread over the surface of the tongue if the irritation be continued. When diffused in this fashion, it constitutes leucoma of the tongue. Leucoma is certainly a predisposing cause of cancer. The smoker should never leave a "patch" untreated, and should avoid rough mouthpieces and brands of tobacco which cause irritation of the tongue.—*Sci.*

NATURE'S TRUE TONIC.—One of the advantages of light gymnastics is that the sick and convalescent can make what appear to be trifling efforts, and by them, in time, be restored to active health. If too feeble to be practically able to make but little exertion, try what are known as deep-breathing movements. Lie flat upon the back, take as long and as deep breaths as possible, and while the mouth is closed, slowly throw the arms up in front and then at the sides. Rest for ten minutes. Try again the same inhalation and exhalation of air, the latter being pure and fresh. After a while attempt the same, sitting up. These exercises can safely be taken by the sick one, every day, several times, and the whole muscular system will be improved, just as if some revivifying tonic had been given, a far better one than any charged with alcohol or some like stimulant.—*Ladies' Home Journal.*

CARBOLIC ACID FOR BOILS.—A German medical journal asserts that incipient boils may be readily cured by the injection of a three-per-cent solution of carbolic acid. In order to effect a radical cure and prevent suppuration, the injection must be made early. If a boil has already begun to discharge, the only effect of the injection will be to hasten the cure and prevent the formation of deep scars.

USEFUL INFORMATION.

How to Make Large Soap Bubbles.

Children, and others, as well, may learn how to prepare a mixture for making the largest kind of soap bubbles, from the following receipt furnished by *St. Nicholas*.—Next to white castile, the mottled castile gives the best results. The soap being obtained, a friendly druggist must carefully weigh out 60 grains (for exactness in proportions is needful) for each ounce of water. That is, one drachm (according to the apothecary's weight of the old arithmetic), and when the weighing is done, and the obliging druggist thanked for kindness, the rest is plain sailing. A bottle with a sound cork is the next requirement. It must be large enough to hold three or four times the quantity of solution you wish to make. Do not prepare too much at one time; two ounces of soap solution will be a good quantity, and for this a six or eight ounce bottle will be the right thing. The bottle must be well cleansed and then well rinsed out with soft water—which, by the way, should be used for all the operations. All being ready, the soap is cut into fragments small enough to enter the bottle. Measure an ounce of water for each drachm of soap; this can be done with a teaspoon, eight spoonful making an ounce. Having poured the water and put the soap into the bottle, we have now to await perfect solution, which will happen in the course of two or three hours, if the bottle be put in a moderately warm place. Then add glycerine to the soap solution, the quantity varying with your ambition. I have found that one-half the volume of the solution gives excellent results; that is to say, to each ounce of water add one-half ounce of glycerine, measuring the quantities instead of weighing them in both cases. The bottle is now to be tightly corked and well shaken; then set aside for two or three hours more, and well shaken again. These alternate periods of rest and agitation should continue for a whole day. Finally, let the bottle stand undisturbed and tightly corked for twenty-four hours. Bubbles of great size and beauty may be blown with this solution.

IRON ALLOYS.—The remarkable success which has rewarded the researches of inquirers and experimenters on the alloys of steel with chromium, tungsten, aluminum and nickel gives good reason to continue exploration of this field. Among these alloys the most important results appear to have been obtained from the use of nickel as an alloy of steel. Iron alloyed with silicon and also with aluminum have many points of resemblance. But when the addition of 15 per cent of aluminum—the minimum amount which has been found efficient implies an addition of something like four dollars per ton to the cost, its employment in competition with silicon as "ferro-silicon," or "silicon speigel," cannot be considered as more than experimental.

A CEMENT that is said to be strong enough to stick anything may be made as follows: Take two ounces of gum-arabic, one and a half ounces of fine starch and half an ounce of fine sugar. Pulverize the gum-arabic and dissolve it in as much water as the laundress would use for the quantity of starch indicated. Dissolve the starch and sugar in the gum solution. Then cook the mixture in a vessel suspended in boiling water until the starch becomes clear. The cement should be as thick as tar and kept so. It should be kept from spoiling by dropping in a lump of gum camphor or a little oil of cloves or sassafras. The cement is extremely strong, and will stick perfectly to glazed surfaces.—*Builder and Woodworker.*

WEALTH IN SEWAGE.—The city of Worcester, Mass., has probably the best arrangement for an economical disposition of city sewage of any other city in the world. After considerable experiment the system is now considered as demonstrated to be an unqualified success. The sewage is collected in large tanks, and when the work of chemical precipitation has been accomplished, the effluent, which is discharged into the Blackstone river, is so pure that chemists say it might be drunk with safety. The system is in use in European cities, and the general verdict there is that its efficiency is unquestioned and its administration economical.

COMPOUND BELTING MATERIAL.—The substitution of camel's hair, cotton, paint and chemicals for leather in machinery belting is meeting with some success in this country. The invention was first perfected in England, where it was received with much favor. It is claimed for the new material that it is stronger than other belting, more durable under strain, more efficient and as low priced, and therefore cheaper in the end.

A PASSENGER CAR without end platforms has been patented by Mr. E. H. Beckley of Elkhart, Ind. At each end of the car are side doors at the bottom of the ordinary steps, the doors being flush with the side of the car and opening inward. The steps may be covered by a trap-door while the train is running. In the end of the car is a door and vestibule arrangement affording communication between the cars.

THE waters of the Seine river, France, have been restocked with 40,000 California salmon.

Passing Events.

Ex-Governor Waterman, whose death is chronicled this week, was as prominently identified with the gold and silver mining interests of California as any man in the State. He was the owner of several productive mining properties in the southern part of California, and a man who was a natural prospector and minor, investing his money freely and developing claims which looked to him promising. To him, more than any other, is due the development of Calico district, San Bernardino county, and the revival of the mines around Julian, San Diego county.

The city is busy with preparations for the reception of the President of the United States, who will remain here and in the vicinity for about a week. On his way here he will visit the prominent points in Southern California.

The discovery of a flow of natural gas at Pleasanton, Alameda county, has caused some local excitement. It is not very strong as yet, but gives promise which has aroused the enthusiasm of the residents. This is only one of several places where natural gas has been found in this State.

The labor troubles in this city still continue, and the building trades are considering the advisability of assisting the molders by refusing

to work on buildings where iron from non-union shops is used. The shoe factories have closed down, throwing a great many out of employment. The situation is discouraging to those who have made investments in local producing industries.

Electric Car Wires.

The supervisors of this city have finally passed an ordinance prohibiting the suspension of electric wires from poles for the purpose of operating cars along the public streets of San Francisco. One company had already spent \$50,000, put up 250 poles on East street, and contracts had been let for upward of one million dollars. The road was to run from San Francisco to San Mateo, 21 miles. The North Beach & Mission Railway also had intended to put in an electric plant. As the 300 electric street railways which have been built in the United States are, with but two exceptions, operated by the overhead wire system, the passage of this order virtually excludes electricity as a motive-power for street-cars in this city, there being no other available practical system.

Arguments were made by the interested parties in favor of the electric roads, but the supervisors considered the poles unsightly and the wires unsafe, so the order was passed.

It will be remembered that the State law was changed recently so as to permit the use of electricity as a motive power on street railroads, but each municipality is empowered to grant or refuse franchises for such roads. Several are being built in and around Oakland and other cities have them in view.

Up to quite a recent date the history of these roads in this State is an unfortunate one. Several were failures and most of them were really built to aid real-estate speculators, and, the property being sold, they were abandoned. As compared with cable roads they are very cheap to construct and equip, but as to comparative cost of operation when finished that is an open question still. The large cities using them are by no means satisfied with overhead wire railroads, notwithstanding the statements to the contrary. For smaller places and suburban localities they answer the purpose very well. In large cities there are several objections to this system and these objections were considered weighty by the Board of Supervisors; hence the passage of the prohibiting order.

The Mechanics Institute Fair.

The Board of Trustees has decided that the 26th Industrial Exposition of the Mechanics Institute shall open on Tuesday, August 18th, and continue until September 26, closing on the evening of that date. The management desire particularly that the arts, industries, new inventions and natural products of the Pacific Coast be well represented, and no pains will be spared to make this class of exhibits a special feature.

The promenade avenues are to be broadened and 4500 seats provided for the comfort and convenience of visitors. Ample motive power, including steam and water, will be provided and furnished in reasonable quantity free to exhibitors, and also special facilities afforded for the testing and operation of new machines and inventions.

Premiums in the form of medals, diplomas and cash will be considered; a band of 50 pieces will furnish music; there is to be a first-rate cafe, and several new and attractive features for amusement and instruction of visitors will be introduced. The management believe the attendance will be greater than at any former fair, making the occasion an exceptional time and place to bring to the notice of the public new inventions, manufactured products, processes and appliances. Exhibits will be received from August 10th to 16th inclusive.

ARTHUR MACY, Manager and Superintendent of the Standard Con. Mine of Bodie, died at San Rafael on Tuesday. Mr. Macy was about 40 years of age, and was a graduate of the Columbia School of Mines. As Superintendent of the Silver King mine in Arizona in its palmy days, he gained quite a reputation. Afterward, as Superintendent of the Standard Consolidated mine, he became even better known. He was very successful in treating the ore of Bodie district.

The President's Visit.

Only once before has a President of the United States, while still clothed with the insignia of that high position, reached our distance from the National Capitol. We have had visits from ex-Presidents and have shown them honors worthy of their public services. President Hayes alone found his way to California while still in office. President Harrison will be the first of all the Presidents to visit the States of Oregon and Washington.

It is but natural that the coming of the chief officer of the republic to our shore should awaken the keenest interest and arouse enthusiasm. Hero worship has prevailed since the beginnings of the race, but in these later days we have come to characterize our deference to those in authority with a wider significance than pertains merely to devotion to the person of the sovereign. We rally to welcome the President as a worthy and honorable citizen, but beyond that our wealth of loyalty and devotion is poured out not upon the man but upon the office which he graces—the headship of our beloved nation. Let not, then, there be any disposition to glorify the coming of President Harrison for fear of sharing the abject devotion which pleased the vanity of the despot. We shall honor Harrison as the embodiment of the American idea and the representative of American greatness. As we believe in that idea and as our patriotism rises into fervor as we contemplate the grandeur of our nation, we cannot refrain from honor to our visiting President. It is but fitting, then, that we show him welcome, hospitality and the fullest goodwill. It is proper that all thought of partisanship should be banished from the popular mind. We honor our institutions and ourselves and we show to the world our faith in them when, as dwellers upon the far-away Pacific, we bestow the highest civic honors upon the visiting chief executive of the nation and demonstrate the fact that though 3000 miles from the nation's heart, the patriotic current is warm and strong and powerful for national unity and harmony.

The President's party is made up as follows: President and Mrs. Harrison, Mrs. McKee, Mrs. Olmick, Postmaster-General Wamaker, Mr. and Mrs. Russell Harrison, Private Secretary Halford, Mr. and Mrs. George W. Boyd, Mr. Tibbitt, the President's stenographer, and several representatives of Eastern newspapers who will accompany the party.

The special train bringing the party is expected to touch California soil at Fort Yuma in the morning of Wednesday, April 22d. It is probable that Governor Markham, Senator Felton and other officials will meet the President at the State line. The following is the itinerary of the California visit:

Arrive at Los Angeles Wednesday, April 22d, at 3 P. M.; arrive at San Diego Thursday, April 23d, at 7:30 A. M.; arrive at Pasadena Thursday, April 23d, at 4:30 P. M.

Leave Los Angeles Friday, April 24th, at 10 A. M.; arrive at Santa Barbara Friday, April 24th, at 2 P. M.

Leave Santa Barbara Friday, April 24th, at 12 o'clock midnight; arrive at San Francisco Saturday, April 25th, at 7:45 P. M.

Sunday, Monday and Tuesday in San Francisco. Leave San Francisco Wednesday, April 29th, at 9 A. M. for Palo Alto.

Leave Palo Alto on evening of Wednesday, April 29th, stop at San Jose and then run through to Santa Cruz.

Leave Santa Cruz Thursday, April 30th, at noon for Monterey; Thursday afternoon and Friday forenoon at Monterey; arrive in Oakland (via San Jose and Niles) Friday afternoon.

Saturday and Sunday in San Francisco.

Leave San Francisco Monday, May 4th, at 2 A. M.; arrive at Sacramento Monday, May 4th, at 6:30 A. M.

Leave Sacramento Monday, May 4th, at 10 A. M., for Portland.

Great preparations are being made for the reception and entertainment of the presidential party in San Francisco. As stated above they will arrive on Saturday and will pass a quiet Sunday.

On Monday there will be a reception to the Governor and staff officers, municipal officers, army and navy officers, consuls, members of the Chamber of Commerce, etc. In the afternoon, from 2 to 5 o'clock, the President will drive through the Park to the Cliff House.

On Tuesday he will participate in an excursion on the bay and visit harbor fortifications. He will be tendered a banquet on Saturday evening, May 2d, after his return from Monterey.

An Ancient Amalgamator.

In looking up the subject of amalgamators, many interesting particulars and devices are to be met with, among which is a patent specification taken out in England in 1783 by Charles, Baron de Chastel, citizen of Geneva. This old machine is on the principle of the older Mexican arsetra and Ohile mill, and really, it is a matter of doubt if there is to-day a better amalgamator than this ancient one, which is described in Florence O'Driscoll's "Notes on the Treatment of Gold Ores," published by John Wiley & Sons. A few extracts from the specification may be of interest. It is set forth "that he, the said Charles, Baron de Chastel, should and lawfully might make, use, exercise and vend his 'New Constructed Machine for Separating Gold and Silver from Earth, Scoria and Impurities, by means of Trituration, Mercury and Amalgama,' within that part of Great Britain called Eogland, the Dominion of Wales, and the Town of Berwick-upon-Tweed.

The specification then continues:

The Baron de Chastel will not confine himself to a specification which tends to move the machine to be constructed; it is a matter absolutely arbitrary, depending upon the locality where the establishment is to be formed; and he thinks that the plans will sufficiently demonstrate of themselves the means that he has made use of. Neither will he limit himself in the manner in which he has laid down the powers of motion. It may be produced by the arms of a man, by means of water, fire, wind, or by the power of a horse, etc. It imports little how it is produced, provided that the means made use of are sufficiently powerful. He will neither specify in what manner the water may be procured; that also is arbitrary. It may be effected by river or rivulets, which, by means of small pipes, may supply the water that may be wanted. In towns, where every house is supplied with water, it will be easy to obtain a sufficient quantity to proceed in the course of that operation which this machine requires; wells may be sunk, pumps, etc. It is easy to comprehend how superfluous it would be to specify all those articles which are absolutely arbitrary, and which enter in the principal of this invention only as collateral matter. Here it is, then, that the Baron de Chastel thinks, only necessary to specify:

Figure 27.

a, brickwork; b, joists and platforms; c, cast-iron basin; d, freestone newett; e, freestones which surround the basin; f, exterior canal out in the said stone; g, mills of cast iron and their trees, the pivots of which are supported in the center; h, wooden circle with its laths; i, iron arm which conducts the mills; l, tree and lantern; m, black tin basin fixed upon the lantern; n, pipes which carry the water into the said basin; o, pipe fixed to the basin m, which carries circularly the water upon the nut d during all the time of the work; p, oblique aperture in the basin of iron; q, oblique aperture in the freestone e; r, a little vault in the said stone to enable it to reach the basin i to draw off the amalgama; s, small basin of freestone; t, concavity in the said basin; u, perpendicular aperture in the said basin; v, canal for carrying off the water into the reservoir, Fig. 28.

Figure 28.

a, brickwork which serves as an inclosure to the reservoir; b, octagonal carpenter's work which supports the freestones c; c, freestones or water conduit; d, large lavigator with its bottom; e, second lavigator without bottom with its laths; f, large cast-iron plate concave in the center, laid on the bottom of the lavigator d; g, cast-iron broyard; h, little cast-iron casement; i, lever to move the broyards; k, cross-piece, which supports the axle tree; l, canal for carrying off the waters and to rid the building of the mud; m, space around the lavigator; n, aperture for drawing off the water from the lavigator or reservoir.

The particulars given in the specification are as to the material, manner of construction, and general remarks about the machine; it is unnecessary to reproduce them, as the reproduced essential parts of the drawings give ample particulars. Excerpts from directions concerning procedure are as follows:

The water which incessantly, during the operation, runs circular on the side newetts, successively carries off the ashes or sands with

Fifth Operation.—When the water is clarified, the amalgam is drawn off by taking away

Sixth Operation.—When it is intended to draw from the great reservoir all the particles that may have escaped from the machines, you will proceed in the following manner: You will supply and clarify the water by turning

retort is customary, and does not enter into the principle to be explained of this new invention.

The Baron de Chastel, after having taken great pains in the researches he has made, after

the spigot, Fig. 1, letter *c*, which closes the aperture of the cast-iron hason. The amalgamized mercury is received into a portable hason; you empty the water of the hason into the little hason, Fig. 27, which passes through the canal into the reservoir, Fig. 28; if any other part amalgamized escape, they precipitate themselves in the concavity of the little hason, Fig. 27. In short, if any of the rich particles escape, they are carried off into the reservoir.

the hroyards all the while; then you will open the aperture marked *n*, Fig. 28, in order to draw off the water, and what remains at the bottom must be taken up with sponges; then the amalgamized mercury, with gold and silver, which will be drawn off at the bottom, must be passed through the skin, as well as that of the machines, in the usual and known manner, to be afterward passed through the report. Remark, this operation of the lam and

having been at great expense, together with his father, to detect all the errors of the ancient mills, which caused so great a loss of precious matter, after having made different trials and different pursuits and experiments upon this subject in the Republic of Geneva, has at length succeeded in the construction of this machine, which promises very considerable advantage. After its first construction made at Geneva, he has still made new trials

and improvements upon this invention, and has made considerable additions and improvements and essential corrections, of which he here has given a specification, so that he believes that this machine is now actually in a very high perfection.

The foregoing drawings and particulars of Baron de Chastel's machine are given principally to show how little advance has been made in this direction during the past 100 years.

This machine has proven successful in several places where used. For all free wash and moderately hard cement it does good work, and must effect a great saving in working such material, owing to the small head of water required. The automatic rejection of all rocks and material by the revolving screen makes the handling of the gravel cheaper, as all hand culling is rendered unnecessary. With from four to six miners' inches of water, 100 tons can be worked every 24 hours. This machine is in use in several places in the State, and represented to be giving satisfaction. There is a wide field for it in the central and northern part of California and Southern Oregon, as well as in other places.

Pulverizer for Auriferous Gravel.

On this page is shown the "Common Sense" pulverizer and concentrator for working auriferous gravel, cement, clay, etc. It does not crush the rocks, but washes them clean, while at the same time it pulverizes the cement or clay and saves the gold, even those particles which are fine.

The machine consists of two iron troughs or "concaves," each 26 inches in diameter, one of which is about 18 and the other 12 feet long. In these troughs are strong revolving shafts with projecting teeth made of steel, two inches wide by three-quarters of an inch thick, placed in spiral form around the shaft about two inches apart, forming a conveyor.

The first shaft is arranged to revolve from 150 to 250 revolutions per minute, and the second one from 300 to 500. There is a revolving screen between the two troughs that takes out the coarser rocks after being washed, and only the finer material runs into the second trough, and is there worked thoroughly.

There is a space of about four inches in the bottom of each trough, or "concave," that fills up with gravel and sand. When the gold is freed it settles into this, and as the teeth do not disturb the bottom, the gold remains there until a cleanup is made.

The concentrating pan shown is used for cleaning up or prospecting where the material does not need breaking up. It is 8 feet long and 2½ feet wide.

The Employers' Federation.

A Federation of Employers is in progress of organization in this city, which will include the foundrymen, ship-owners, lumber dealers, box-makers, huddlers, harness and leather-makers, etc. The idea is to form a federation of employers of the Pacific Coast on the same plan and to be just as extensive as the organization of trades unions in the Council of Federated Trades, with its sub-federations in all parts of the coast, so that, no matter in what trade or locality the Council of Federated Trades might exert its power, it would meet an equally compact organization to oppose its decrees. It is not proposed to attempt to destroy trades unions, but to restrain them and to resist unreasonable demands; nor is it desired to reduce wages, but to so arrange matters that employers shall not be dictated to as to the individuality of employes. A committee is to be appointed, selected from the different industries, which will constitute a court of final appeal in disputes. The decision of the committee will have the power of the federation to sustain it.

A committee has been appointed to draw up a declaration of principles and Constitution and By-laws, and the report is about ready, so that the organization will soon be perfected. It will answer for this locality the purpose that the Australian federation does in that country. The trades unions have become so strong, and some of their demands so arbitrary, that those who have capital invested in industrial enterprises consider it necessary to combine together for mutual protection and benefit.

Founded by Mathew Carey, 1785.

Mining and Hydraulic Engineer,

No. 307 Sansome St., SAN FRANCISCO.

The instrument represented in the above cut is a
new and grand little invention, being designed to
save life and limb, and innumerable lawsuits, by
doing away with the dangerous operation of digging
out wet and unexploded loads where Giant Powder
is used in mining. The little instrument crimps the
cap on to the end of the fuse firmly and a so-
lutely Water-tight. It is also used for cutting
the fuse. They are neatly gotten-up of the finest
cast steel, nickel plated. Price, \$2 each, or the
entire instrument finished in gold plate, \$5.

MARKET REPORTS.

Local Markets.

SAN FRANCISCO, April 16, 1891.

General trade continues fairly active. Rains in the valleys the past week give stronger assurance of large crops, and as prices average well, a prosperous year with farmers can be predicted with the utmost confidence, and of course as farmers and miners prosper, so do other industries. The local money market is easy. Quarterly dividends are being disbursed which is an important factor in promoting an easy money market. Manufacturers appear to be greatly encouraged, notwithstanding labor strikes. Owing to cheap coals, iron, etc., bountiful harvests and water are assured in mining districts.

MEXICAN DOLLARS.—The market is essentially unchanged, being dull around 78 cts. The China steamer took out \$45,372 for China, and \$100,000 for Japan.

QUICKSILVER.—Receipts the past week aggregate 208 flasks. For the week ending April 9th exports by sea aggregated: Mexico, 100 flasks; Auckland, 10; and Mazatlan, 30. For the week ending to-day (16th) no exports are reported. The overland shipments for March aggregated 157,500 lbs. The market is reported unchanged with more or less cutting reported.

SILVER.—Purchases by the Department are reported as follows in this month:

Date.	Offered ounces.	Purchased ounces.	Price paid per ounce.
April 3.....	915,000	370,000	\$98200 to \$98375
April 8.....	400,000	400,000	\$97900 to \$98000
April 13.....	242,000	242,000	\$97800 to \$98050

Shipments by sea the past week aggregate, to Japan, 35,000 ounces and Bombay, 49,850.

The market has gradually fallen, until on yesterday (Wednesday) New York came through at 97 3/4 cts. The decline to many is unaccountable, with the Government purchasing 4,500,000 ounces a month and the output of the mines in this country claimed to be less than last year. On this coast we know that the production is less. There can be no doubt but European war rumblings have much to do with the market. The Continental nations, notably Russia and Germany, are increasing their stocks of gold; but while doing this there is nothing to warrant the belief that they are unloading their silver. But the fact that they are hoarding gold gave to purchasers and also the bear contingent a handle to knock silver down. It looks as if securities abroad, based on the market price of silver, are being quietly absorbed for a grand speculative boom later on, and when things are in condition for the bull campaign, silver will be advanced. The taking of gold from this country, contrary to Wall street opinions when silver was under discussion by Congress, does not make a ripple in the financial circles, for they know that it and more besides will come back in due season.

BORAX.—Receipts the past week aggregate 437 cts. The overland shipments in last month aggregate 640 cts. The market is fairly steady.

LIME.—Receipts the past week aggregate 3626 bbls, and exports by sea 715 bbls to Hilo and 200 bbls to Kahului. The home demand continues fair. The market is reported unchanged.

ANTIMONY.—It is claimed that purchases can be made below our quotations.

TIN.—Imports the past week aggregate 400 bxs. overland. For pig the market is quiet. The tone is barely steady. In plate, an active consumption is reported, but supplies were generally thought to arrive, consequently the market does not show it. Eastern and European advices report lower prices for pig under a decline in silver and more offering.

LEAD.—The market with us continues unsettled, with concessions obtainable. At the East the market appears to be of a waiting character, and any selling pressure is met by lower bids.

COPPER.—The market is barely steady. Eastern and European advices are confirmatory of an unsettled feeling in trade. There are rumors afloat and which are noted in best informed papers at the East, that indications point to a move to concentrate stocks and control the output.

IRON.—Stocks are large, as are consignments to arrive. The market is weak, with concessions obtainable.

COAL.—Imports the past week aggregate as follows: Newcastle, N. S. W., 6076 tons; Coos Bay, 950; Departure Bay, 3333; Seattle, 1340; Nanaimo, 1378. Total, 13,077 tons. The market has held barely steady. Light imports admit of working off spot and near by arrivals to better advantage. Dealers and large consumers do not appear disposed to anticipate their wants to any great extent, unless offered inducements. An improvement in crop prospects in this State and an almost certainty of a large wheat crop, cause coal buyers to be offish in making bids for forward shipment. They think that after May there will be free offers to coal for shipment to this port.

Eastern Metal Markets.

By Telegraph.

New York, April 16.—The following are the closing prices the past week:

	Silver in London.	Silver in New York.	Copper.	Lead.	Tin.
Thursday.....	97 3/4	97 3/4	13 7/8	4 3/8	20 20
Friday.....	97 3/4	97 3/4	13 7/8	4 3/8	20 10
Saturday.....	97 3/4	97 3/4	13 7/8	4 3/8	20 10
Monday.....	97 3/4	97 3/4	13 7/8	4 3/8	20 10
Tuesday.....	97 3/4	97 3/4	13 7/8	4 3/8	20 10
Wednesday.....	97 3/4	97 3/4	13 7/8	4 3/8	20 10

Quicksilver continues in buyers' favor. Tin is lower and weak. Copper quiet at 13 3/4 for lake, 13 1/2 for Arizona ingot and 11 1/2 for casting brands. Lead less active and rather weak at 4 3/8 for domestic. Spelter, 5 1/2 @ 5 1/2, with small sales and the market depressed. Iron dull and generally unchanged, but the tendency of prices is believed to be downward. No. 1, Northern or Southern, \$17.50 @ 18; No. 2 do., \$16.50 @ 17. Steel rails quiet at \$30.

IN CONSEQUENCE of the strike against Buckingham & Hecht, the other three factories in the Shoe Manufacturers' Association closed Saturday night for an indefinite period. One thousand men, women and boys are thrown out of employment.

List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific Coast.

FOR WEEK ENDING APRIL 7, 1891.

- 449,996.—PROPELLER—O. J. B. Boeslager, Mount Angel, Or.

 449,787.—ROW LOCK FOR BOATS—Jas. Williams, Portland, Or.
 450,092.—SLATE ATTACHMENT—Maud Wyman, Oakland, Cal.

The following brief list, by telegraph, for April 14 will appear more complete upon receipt of mail advices: California—Fred Bommemann, San Francisco, child's folding carriage; George R. Dural, assignor to the Benicia Agricultural Works, Benicia, traction wheel; Charles W. Harvey, Los Angeles, and C. J. Root, Bristol, Conn., said Root assignor to said Harvey, door spring; Charles S. Jones, Redding, Ore. mill; John C. Scudder, Dover, N. J., assignor to Repanno Chemical Company, Wilmington, Del., and Atlantic Dynamite Company, San Francisco, apparatus for making dopes for explosives; Henry E. Thomas, assignor of one-half to F. H. Hansman, San Francisco, self-power pump; Hilbert Tompkins, San Leandro, foot-strap for horses. Oregon—Langley Hale Jr., Glendale, assignor of one-fourth to G. A. Taylor, Roseburg, Ore. axle.

Washington—Joseph H. Bradshaw, assignor of one-fourth to J. Willey, North Yakima, barnes.

NOTE.—Copies of U. S. and Foreign patents furnished by Dewey & Co. in the shortest time possible (by mail or telegraphic order). American and Foreign patents obtained, and general patent business for Pacific Coast inventors transacted with perfect security, at reasonable rates, and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

GANG-PLOW.—James and William Paterson, Stockton, assignors to the Benicia Agricultural Works of Benicia, Cal. No. 449,329. Dated March 31, 1891. It consists of a main frame, to which the power is applied for moving the plows, said frame being binged in a central longitudinal line, so that there are two flexibly-joined sides, and diagonally-arranged supporting-timbers, to which the plows are attached in line together, with bearing wheels by which the depth of the plows upon the two sides may be independently gauged. By this construction the inventors counterbalance the plows by extending one series each side of the central timbers and by binging these timbers together and journaling upon them the bearing wheels with their respective operating levers they are enabled to raise or depress either end or the central portion of the frame and the plows connected therewith while by means of the jointed or flexible attachment of the two-part frame, a wide plow is allowed to adjust itself to variations in the surface of the ground.

CONSTRUCTION OF BUILDING.—Peter H. Jackson, S. F. No. 449,323. Dated March 31, 1891. In a former invention patented by the same inventor (July 22, 1884, No. 302,338) there was shown a riser-beam extending along the front of the elevated area and forming a step and support for the sidewalk and illuminating-surfaces and in connection therewith a beam-support and intermediate brackets by which the two are united. In the present invention the inner end of the sidewalk or illuminating surface is sustained directly, or nearly so, in line with the greatest strength of the supporting beam, and the tendency to a side and twisting strain which was developed in the former construction, is avoided. By the construction adopted, the sidewalk or illuminating surface is supported upon the lower flange of the beam, the principal depth of the beam extending above this point, and as there is very little of the beam projecting below it will not cut off the light and prevent its entering the space beneath and to the rear. This construction is simpler and more economical than any heretofore employed.

DEVICE FOR DRAWING STEAM BEER.—Constant Harth, Willows, Colusa Co. No. 449,853. Dated April 7, 1891. This invention relates to a device for drawing beer under a heavy head or pressure of gas. This class of fresh beer is known as "steam beer" in distinction from lager and other kinds, which take longer in making and have not so great a pressure of gas in them. This beer is usually made and placed in casks of various sizes which are delivered in places where the beer is to be sold by the glass, and the beer is drawn directly from the cask. The pressure of the gas is, however, so great that it is impossible to draw the beer without allowing some of the gas to escape and after the cask is more than half empty there is not pressure enough of gas to keep the beer in a sufficiently lively condition. This invention consists in the interposition of a chamber or receiver between the cask and the drawing g-off faucet and a means for conveying the

beer from the cask to this chamber and from the chamber to a peculiarly constructed drawing-off faucet which is used in connection therewith.

DENTAL ENGINE.—John W. Gibson, S. F. No. 449,848. Dated April 7, 1891. The object of this invention is to provide a dental-engine bracket which is adapted to be turned both horizontally and vertically, and also to provide simple and effective means for readily reversing the motion of the engine.

SAW-GUIDE.—Wm. A. Campbell, Portland, Oregon. No. 449,844. Dated April 7, 1891. The object of this invention is to provide a simple and effective saw-guide in which the opposing guides are readily adjustable to graduate the space between them, both guides being also movable in the same direction in order to throw the saw out of or in the cut, and the outer guide being adapted to be readily moved out of the way to change the saws.

ELECTRICAL DENTAL ENGINE.—Frank F. Eggers, S. F. No. 449,847. Dated April 7, 1891. This electrical dental engine consists of a motor journaled and rotating directly in the movable bracket of the apparatus, a means for stopping and reversing said motor, and in disengaging it from the mechanism which it drives, together with an extension for the bracket and its connections. The object is to combine in a single mechanism an adjustable dental bracket and a motor by which the flexible shaft which carries the various tools may be driven, a means for instantaneously disengaging the motor from the shaft, so that the latter will not be driven by the momentum of the motor, an extension mechanism for the bracket, and a switch whereby the direction of rotation of the motor may be changed at will.

AUTOMATIC BELL-RINGER.—Wm. W. Slater, Oakland. No. 449,866. Dated April 7, 1891. This is an improvement on a device for which letters patent were issued to the same inventor, Aug. 6, 1889, and it consists essentially in simplifying the number of parts and making a more direct connection for operating the clapper of the bell. It is especially intended to ring cautionary or alarm bells, such as are employed at railroad crossings and for similar purposes. It consists of a bell fixed to a suitable support having a swinging tongue or clapper and an air-actuated mechanism whereby the clapper is caused to swing, an electro-magnetic device whereby the valve is opened and closed and a means for alternately making and breaking the circuit for this purpose.

RIDING PAD.—Wm. C. McFeely, Sacramento. No. 449,860. Dated April 7, 1891. This is a device to take the place of a lady's side-saddle. It can be used with or without a blanket or saddle; and may be used in connection with a gentleman's saddle, thereby enabling a lady rider to use such a saddle and have her limbs suitably supported by the pad which occupies a space in front of the saddle when the latter is used. The device is light and contains the necessary elements of safety and at the same time is suitable for the horse's back.

STUMP-PULLER.—Wm. B. Morris, Seattle, Wash. No. 449,858. Dated April 7, 1891. Mounted on a sled so as to easily hauled over the ground is a vertical shaft suitably braced, and on this revolve two rope-winding drums of slightly different diameter. One portion of the rope is wound around the larger part of the drum and the other portion around the smaller part from the opposite direction so that when this drum is turned around, the rope unwinding from the small part of the drum will be wound up somewhat faster upon the larger part, and the difference in size of the two drums determines the amount of power which is applied. The light of the rope passes through a pulley-block, and from the hook on this block a chain extends to the stump that is to be pulled. The gearing is so arranged that a horse may walk around with the lever, or it may be operated reciprocally as desired. The device is light, powerful and effective.

Complimentary Samples.

Persons receiving this paper marked are requested to examine its contents, terms of subscription, and give it their own patronage, and, as far as practicable, aid in circulating the journal, and making its value more widely known to others, and extending its influence in the cause it faithfully serves. Subscription rate, \$3.00 a year. Extra copies mailed for 10 cents, if ordered soon enough. If already a subscriber, please show the paper to others.

Mining Share Market.

Comstock mining shares the past week showed continued activity. All shaded off on Thursday and Friday, but the Middle and Gold Hills lost the largest per centage. On Friday afternoon Con. Virginia and Overman showed considerable strength at a slight advance which was followed on Saturday by slightly better prices along the entire line. On Monday the market opened higher for the North Ends and stronger prices for others. In the afternoon Ophir took the lead and sold for more money. On Tuesday Best and Belcher, Ophir, Con. Virginia and Mexican made a jump ranging from 10 to 15 per cent, and other stocks from 5 to 10 per cent. Tuesday afternoon Hale and Norcross moved up 20 per cent on morning prices. This advance caused more strength in other Middle stocks. Wednesday morning there was a further advance in the Middle under the leadership of Hale and Norcross. The Gold Hill stocks advanced slightly, but the North Ends held around at Tuesday's higher prices. The present higher end more active market, made so chiefly by cross-orders, does not appear to draw in new moneyed outside operators. The little trading being done by outsiders is confined largely if not entirely to habitual traders; and it is not these for they have not the money, that manipulators are seemingly trying to unload on, so as to collect assessments. Until manipulators succeed in unloading, it is reasonable to conclude the market will go higher, but when outsiders do take the stocks it is equally as reasonable to believe that the market will go down at a break neck speed, so as not to let them get out except at very low prices. This is the history of all former deals, and the present will be no exception.

Yellow Jacket, Chollar, Scorpion and East Sierra Nevada were assessed the past week. It is said in well informed quarters that assessments will be levied soon by several other companies. While insiders have the stocks, the assessments will do no harm to the market; it is only when stocks are well out that assessments send prices down. It now looks, as the writer has stated, that the market will go still higher although small set backs can be expected, until the pools unload, when a rapid decline of from 50 to 75 per cent from top prices can be looked for.

Outside shares have been dull and lifeless. It looks as if manipulators in them are waiting for the Comstocks to have this deal before attempting an up move.

The mining share market opened this (Thursday) morning slightly higher. After Call the market shaded off, but toward noon began to recover. The Quijotas developed more strength, but this is to be expected, for in all cases where stocks are concentrated, it is in order to strike rich ore, start up the mill or do anything to unload at higher figures.

The news from the Comstock mines reports an improvement in Hale and Norcross. The improvement is said to be in a winze, but if readers of this paper will refer to their back files of the PRESS, they will find where it is or will be when the deal; is well under way. Yellow Jacket's strike of rich ore, made some time ago, has brought the usual result—an assessment, but the ore is still in the mine. In Belcher's official letter an improvement is reported, which is liable to develop into something of importance. In Crown Point they are running for the west ledge on the 1000-foot level. In Ophir, and Best and Belcher they ought to report ore soon. Reliable advices from Con. Virginia continues to indicate that the work is developing a veritable rich mine. They also warrant our asserting that the assays ought to be higher. The Gould and Curry ore is being shipped to the Nevada mill. The assays should go high. Ophir has several hundred tons of ore taken out going from \$25 to \$45 a ton. Good news is expected soon from Porosi and Bullion. Con. Imperial continues to send ore to the mill. In last month 615 tons were milled, the bullion from which gave a net return after minting of \$13,735. The Overman mine continues to attract attention. The Alta group is being closely watched by miners.

THE Round valley coal lands are said to be now entirely owned by Flood and Mackay. The Enreka (Humboldt Co.) Standard says the deed calls for 23,362 acres of coal lands.

MELVILLE ATTWOOD, the mining engineer, has gone to Washington to examine a coal property.

NEWSPAPER AGENTS WANTED.

Extra inducements will be offered for a few active canvassers who will give their whole attention (for a while at least) to soliciting subscriptions and advertisements for this journal and other first-class popular newspapers. Apply soon, or address this office, giving address, age, experience and reference. Special inducements to old agents.

DEWEY & Co., Publishers,
No. 220 Market St., S. F.

Don't Fail to Write.

Should this paper be received by any subscriber who does not want it, or beyond the time he intends to pay for it, let him not fail to write us direct to stop it. A postal card (costing one cent only) will suffice. We will not knowingly send the paper to any one who does not wish it, but if it is continued, through the failure of the subscriber to notify us to discontinue it, or some irresponsible party requested to stop it, we shall positively demand payment for the time it is sent. LOOK CAREFULLY AT THE LABEL ON YOUR PAPER.

Assessment Notices.

GRAY EAGLE MINING COMPANY.—Location of principal place of business, San Francisco, California. Location of works, Placer County, California. Notice is hereby given, that at a meeting of the Board of Directors, held on the 3d day of April, 1891, an assessment, No. 23, of Three (3) Cents per share, was levied upon the Capital Stock of the Corporation, payable immediately in United States Gold Coin to the Secretary, at the office of the Company, Room 11, No. 313 California Street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 15th day of May, 1891, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on TUESDAY, the 9th day of June, 1891, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.
A. W. BARROWS, Secretary pro tem.
Office, Room 11, No. 313 California Street, San Francisco, California.

INYO MARBLE COMPANY.—LOCATION of principal place of business, San Francisco, California. Location of works, Inyo County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 30th day of March, 1891, an assessment (No. 12) of Ten Cents per share was levied upon the Capital Stock of the Corporation, payable immediately in United States Gold Coin to the Secretary, at the office of the Company, 132 California Street, San Francisco, California. Any stock upon which this assessment shall remain unpaid on the 12th day of May, 1891, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on FRIDAY, the 2nd day of May, 1891, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.
G. W. LUCE, Secretary.
Office, 132 California Street, San Francisco, California.

CARMELO LAND AND COAL COMPANY.—LOCATION of principal place of business, San Francisco, California. Location of works, Monterey County, California.

Notice is hereby given, that at a meeting of the Board of Directors, held on the 11th day of April, 1891, an assessment, No. 3, of Fifty Cents per share, was levied upon the Capital Stock of the Corporation, payable immediately in United States Gold Coin to the Secretary, at the office of the Company, Room 9, 324 Pine Street, San Francisco, California. Any stock upon which this assessment shall remain unpaid on the 16th day of May, 1891, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on TUESDAY, the 16th day of June, 1891, to pay the delinquent assessment, together with costs of advertising and expenses of sale. By order of the Board of Directors.
W. T. BAGGETT, Secretary.
Office, Room 9, 324 Pine Street, San Francisco, California.

ELECTRIC BLASTING.

VICTOR ELECTRIC PLATINUM FUSES.
Superior to all others for exploding any make of dynamite or blasting powder. Each fuse folded separately and packed in neat paper boxes of 50 each. All tested and warranted. Single fuses sold at strength, with any length of wires.

VICTOR BLASTING MACHINE. Made in two sizes. No. 2 fires 20 to 30 holes. No. 1 fires 5 to 8 holes. Adapted for prospecting, stump blasting, quarry and general railroad work.

"PULL UP" BLASTING MACHINE.—The strongest and most powerful machine ever made for Electric Blasting. No. 4 fires 70 holes. No. 3 fires 40 holes. Are especially adapted for submarine blasting and large mining work.

Standard Electric Fuse and Blast Tester Wire.
Reels, new design, Lending and Connecting Wire.

MANUFACTURED ONLY BY

Dewey & Co.'s Scientific Press
Patent Agency.

OUR U. S. AND FOREIGN PATENT AGENCY presents many and important advantages as a Home Agency over all others, by reason of long establishment, great experience, thorough system, intimate acquaintance with the subjects of inventions in our own community, and our most extensive law and reference library, containing official American and foreign reports, files of scientific and mechanical publications, etc. All worthy inventions patented through our Agency will have the benefit of an illustration or a description in the MINING AND SCIENTIFIC PRESS. We transact every branch of Patent business, and obtain Patents in all countries which grant protection to inventors. The large majority of U. S. and Foreign Patents issued to inventors on the Pacific Coast have been obtained through our Agency. We can give the best and most reliable advice as to the patentability of new inventions. Our prices are as low as any first-class agencies in the Eastern States, while our advantages for Pacific Coast inventors are far superior. Advice and Circulars free.

MARSHUTZ & CANTRELL, Sole Manufacturers.

The Patentee and Manufacturers cordially invite miners to critically examine and pass judgment upon this improved system of milling and amalgamating ores in the following particulars:

1. The cost is less than one-half of stamps of same capacity.
2. The freight to mine is less than one-half of stamps.
3. The cost of erecting is less than one-fourth of stamps.
4. The power to drive it is less than one-half of stamps.
5. The wear is less than one-quarter of stamps.
6. There is no wear except on shoes and dies.
7. In point of amalgamation it is superior to any other machine in use.
8. In its simplicity of construction.

We challenge competition with Stamps, Ball Pulverizers or and other ore crushing machines now before the public.

Send for Circulars and Price List.

IMPROVED BELT FRUE ORE CONCENTRATOR.

The Best Ore Concentrator in the market, having double the Capacity and doing its work as close as the plain Belt machine, while its concentrations are clean. It is used in a number of Mills, the most notable of which is the Alaska M. & M. Co's Mill, where 24 Improved Belt Frues are taking the Pulp from 120 Stamps, crushing 350 tons per day, and is giving entire satisfaction as against 48 plain Belt Machines, taking the Pulp from the other 120 Stamps.

Price of Improved Belt Frue Vanner, \$825, f. o. b.
Price of Plain Belt Frue Vanner, \$575, f. o. b.

For Pamphlets, Testimonials and further information apply at office.

ADAMS & CARTER, Agents FRUE VANNING MACHINE CO., Room 15, No. 132 Market Street, San Francisco, Cal.

Protected by Patents December 22, 1874; September 2, 1879; April 27, 1880; March 22, 1881; February 20, 1883; September 18, 1883; July 24, 1888. Patents applied for.

There are Over 2200 Plain Belt Machines now in Use.

THE MONTANA COMPANY (Limited), London, October 8, 1885.
DEAR SIRS:—Having tested three of your Frue Vanners in a competitive trial with other similar machines (Triumph), we have satisfied ourselves of the superiority of your Vanners, as is evidenced by the fact of our having ordered 20 more of your machines for immediate delivery. Yours truly, THE MONTANA COMPANY (Limited).

N. B.—Since the above was written the 20 Vanners, having been started, gave such satisfaction, that 44 additional Frues and more stamps have been purchased. ADAMS & CARTER.

"TRIUMPH" ORE CONCENTRATOR WITH IMPROVED RIFFLED BELT.

The competitive trials which have been held between the "Triumph" Ore Concentrators, the "Frue" Vanners and other forms of concentrating devices, do not warrant the assertion that the "Frue" Vanner is the best ore concentrator in the market. The fact that the "Frues" have improved (corrugated) belts does not militate against the superiority of the "Triumph"; for, when desired, they (the "Triumphs") can be mounted with a superior belt known as the "Blasdel" Riffled.

Price "Triumph" Concentrators, with Improved (Patented) Belt - - - \$650 f. o. b.
Price "Triumph" Concentrators, with Plain Belt - - - - - \$550 f. o. b.

We are prepared to guarantee the superiority of the "Triumph" over the "Frue" or any other form of Concentrator, for coin if need be. Circulars and testimonial letters furnished on application.

JOSHUA HENDY MACHINE WORKS,
39 to 51 Fremont Street, San Francisco, Cal.

(PATENTED.)

Both the "Triumph" Concentrator and "Blasdel" (riffled) Belt are protected by incontestable letters patent, granted by the Government of the United States.

Original Empire Mill and Mining Company,
Principal Office, 401 California St., cor. Sansome, S. F.
Location of Works, Grass Valley, Nevada Co., Cal.
GRASS VALLEY, NEVADA CO., CAL., Nov. 10, 1885.

Joshua Hendy Machine Works, 39 to 51 Fremont St., S. F., Cal.:
GENTLEMEN—I am pleased to state, in reference to the "Triumph" Ore Concentrators, that four (4) of them were placed in the mill of the Original Empire Mill and Mining Company in April, 1884, and a thorough test made of their practical operation; and their efficiency having been demonstrated, four (4) more were subsequently introduced as the complement of the Twenty (20) Stamp Mill, and the eight (8) have been and are now running with entirely satisfactory results.

At the Ten (10) Stamp Mill of the North Star Mining Company, under my supervision, four (4) are also in successful operation, and from my observation of their practical workings, I am convinced that this form of Concentrators is the equal, if not superior to any other style of Vanners or concentrating devices. DAVID McKAY, JR.,
(Signed) Sup't North Star and Original Empire Mining Co.

N. B. When the stamping capacity of the two above named mills was increased, more "Triumph" Concentrators were purchased, and twenty-eight (28) are now in constant successful operation.

Quartz-Crushing Appliances.

One of the engravings on this page shows the high-class Cornish rolls manufactured by the Riedon Iron Works of this city. Cornish rolls are sometimes used instead of stamps for dry pulverizing of ore after it has passed the rock-breaker. Two sets are generally used—the roughing and the finishing, roughing rolls taking the ore from the crusher, delivering it through revolving screens, from whence all that is too coarse for the roaster or jig is returned to the finishing rolls, which are adjusted to reduce the ore to the desired fineness. Any ore still too coarse can again be returned to these or another set of finishing rolls. Rolls can be used to best advantage in large mills, where they can be worked continuously to their full capacity. The rolls shown in the engraving are of the best design, strong and durable. Ten sets of these rolls were made by the Riedon Works for the Anaconda mine, Montana. The other engraving shows a type of ore crushers made by the same works.

Government Ships Built Here.

The armored coast defense vessel Monterey, which will be launched from the Union Iron Works' yard on Tuesday next, in the presence of the President and party, will be a more powerful ship than many suppose. Her length over all is 261 feet; load water line, 256 feet; extreme beam, 69 feet; mean draft, 14 feet 6 inches; displacement, 4000 tons; armor belt amidships, 13 inches thick; estimated speed, 16 knots.

Her armament consists of two 12-inch breech-loading rifled guns, with 13-inch steel armor protection; shield 8 inches thick; projectile

weighs 850 pounds; powder charge, 425 pounds. Two 10-inch breech-loading rifles mounted en barbette, 11½ inch steel armor protection; steel shields, 7½ inches in thickness; projectile

weighs 500 pounds; powder charge, 250 pounds. She also has six 6-pound rapid-firing rifles; four 37-millimeter Hotchkiss revolving cannon and two 1-pound rapid-firing rifles.

It will be seen that this vessel is of comparatively light draft, being very full and round, something in shape like a center-board sailing vessel. She has very small free board, that is, low sides above the water. There are two turrets with conical tops.

This is the third of the cruisers built by the Union Iron Works in this city, the Charleston and San Francisco having been completed, and the Monterey ready to launch. "Cruiser No. 6" and the "battleship" Oregon are still to be built. The Charleston is 3780 tons, San Francisco 4080 tons, Monterey 4000 tons, Cruiser No. 6 5800 tons, and Oregon 10,250 tons.

The contract for the Monterey was signed June 14, 1889. The first frame was laid October 7th, and first keel-plate laid on December 20th of that year. The first rivet was driven January 10, 1890, first frame raised January 16, 1890, and the launch will take place April 28th.

THE IDAHO MINE.—The new ore body that is now being opened up on the No. 18 level of the Idaho mine, Grass Valley, promises to be very important, as the quartz shows finely in free gold and carries well in high-grade sulphurets. Supt. Edward Coleman regards this new ore body as a distinct shoot from the regular shoot from which such a large amount of gold has been taken, and although not disposed to be over-enthusiastic in reference to it, says he regards it as an important development, and one which may prove of value in the future working of the mine. The depth at which this new shoot is found is about 2000 feet vertically from the surface, or 2700 feet on the incline.

THE NEWEST WORKS OF THE SOUTHERN PACIFIC CO. at Oakland will soon be in operation. The works are intended to prepare piles and timbers exposed to dampness, so as to preserve them.

IMPROVED ROCK-BREAKER.

HIGH-CLASS CORNISH ROLLS FOR ORE.

CORRESPONDENCE.

We admit, unindorsed, opinions of correspondents.—EDS.

Loss of Gold.

[Written for the MINING AND SCIENTIFIC PRESS by
C. H. AARON.]

I think the article on this subject in your issue of 11th inst. by Mr. A. B. Paul is well worth the attention of gold millmen. It is true that in the very few instances where I have had occasion to know, the loss of gold was not heavy; but I have had little to do with ordinary gold milling, and Mr. Paul's statements are not to be questioned, being based on experiments made in a satisfactory manner. It must be admitted that in the month's run of the celebrated Spanish mine, the results of which I investigated and reported for the State Mining Bureau in 1888, more gold was lost than saved, but the original contents of the rock were so very low that they could hardly have been better worked with any hope of profit. Some years ago I was employed to investigate the working of a gold mill in this State, the owners of which thought their rock was much richer than it was, and were not satisfied with the returns. I took samples of the rock coming from the breaker and from the discharge at the end of the tailrace, beyond the Hendy concentrators and blanket sluices. I think I know how to take samples of tailings. Only clear, settled water was poured off; the remainder was holed to dryness. I did this during two days, my samples being quite large; that of the rock was of several hundred pounds weight.

My assays showed that the rock contained about \$11 per ton; the tailings about 30 cents per ton. The gold was not generally visible in the rock, and a part of it was in sulphurets.

I reported to my employers that the mill was doing satisfactory work, and if they were not getting the proper quantity of gold, it was because they were being robbed. This idea they could not entertain, as the mill foreman was a very pious gentleman who would never let the mill run on Sunday. They paid me for my services, but I thought they did not seem to be satisfied. About a month later it transpired that the pious millman used to devote Sunday afternoon to a partial cleanup of the mill on his own account! This shows that the losses in gold-milling are not always due entirely to flotation, rusty gold, etc.

As to dry amalgamation, I think Mr. Paul first got the idea in 1867 at the Silver Sprout mill. At all events, prior to that date, a gentleman told me that he had tried dry amalgamation of raw sulphurets in an arrastra with excellent results, except the difficulty of recovering the quicksilver. This difficulty, it seems, Mr. Paul has overcome, and I think he is very likely to be right in saying that his method is the best for high-grade rock. I also think he is right as to the advantages of the arrastra in the treatment of rock of a moderate grade of richness, the limit depending on circumstances, and here I will once more suggest, as I have done before, that those who are amalgamating gold in arrastras or pans should try the effect of adding to the pulp a little solution of cyanide of mercury in cyanide of potassium.

In this solution gold is positive to mercury, consequently gold precipitates mercury upon itself, and every particle of the precious metal in the pulp so treated becomes amalgamated on its surface, and, in this condition, readily adheres to and sinks into a mass of mercury on contact. Gold, which mercury will not touch, even with the aid of cyanide of potassium alone, amalgamates readily in this way. The method might possibly be applied in battery amalgamation also, if the water were saved and used continuously.

The "medicine" should not be used too freely as it dissolves gold in exact proportion to the precipitation of mercury, though, however, it is very likely that the dissolved gold may be recovered by the use of a little zinc amalgam in the pan or arrastra, as zinc precipitates both metals from the cyanide solution, though iron does not, hence the process may be used in an iron pan, or in Paul's Americanized arrastra.

I think the solution is most cheaply and conveniently obtained by dissolving the red oxide of mercury in a solution of cyanide of potassium. The latter must be in excess, as cyanide of mercury alone does not deposit on gold. The solution may be tested by putting a drop of it on a gold coin and slightly warming the coin. In a very short time the spot where the drop is will be whitened.

Red oxide of mercury costs about 90 cents per pound, and cyanide of potassium for milling about 40 cents per pound. As a very small quantity will suffice for a ton of ore, it cannot be very expensive and is certainly worth trying. I should be gratified, and others would be benefited, if any person who may make the experiment in practical working would report results through the MINING AND SCIENTIFIC PRESS.

It is important that the pulp shall not contain an acid salt, and, as gold rock containing sulphurets is pretty sure to form a pulp containing sulphate of iron, it will be best to add a little lime, soda or ash before putting the "medicine" in, so as to make the pulp faintly alkaline—that is, so that it will make reddened litmus paper become purple or blue.

Even when this solution is not used, I think it would be desirable to make the pulp slightly

alkaline by means of ashes, soda or potash, because it has been shown that sulphate of iron is injurious in amalgamation. Cyanide of potassium alone can dissolve fine gold, hence those who use it in pans or arrastras should not omit to add also some zinc amalgam, which is easily made by warming some mercury and adding metallic zinc.

Nevada County's Mines.

[From Our Traveling Correspondent.]

Grass Valley.

EDITORS PRESS:—In the early history of quartz mining in Nevada county, the mining operator abandoned a mine whenever the pay gave out. There was a general disposition to retain all that had been extracted from the quartz and a general disinclination to expend a dollar in further prospecting. As the result, mine after mine was "worked out" (?) closed down and abandoned. In time these worked-out mines were reopened and a comparatively small amount of work showed up large bodies of ore as rich or of still greater value than those originally exploited. This success stimulated others, and gradually, one by one, the old mines were taken hold of, until to day there is scarcely a mine in the vicinity of Grass Valley that is idle. On every hand the new hoist or mill greets the eye and the people all have that confidence following continued success that leads them to believe that in depth every mine in the section will prove of value. This general activity among all the mines has its effect on the town as well, and the stranger soon feels that Grass Valley has some solid backing to produce the business prosperity of the city.

It is the opinion of every one that there has never, in the history of quartz mining, been a time in this section when the outlook and present condition was as promising and prosperous as right now.

The early history of the different mines is so generally known to the readers of the PRESS that it is not necessary to go into the past, but rather to give a short description of the present condition of the working mines visited by your correspondent.

The Idaho.

Edwin Coleman, superintendent enjoys the enviable distinction of being the deepest dividend paying gold mine in America. The past history of the mine is in keeping with the present, with every assurance that the future shall equal it in the regularity and amount of dividends. The mine is operated by an incline shaft which at this time is about 2,400 feet on the vein or 2,000 feet vertical. The vein at this time is averaging two feet at bottom of shaft, the ore carrying about one per cent of sulphurets that go \$80 to the ton. The vein matter now averages \$15 to the ton. The vein in the Idaho gave out in a manner similar to all the mines of Grass Valley, at 1,600 feet and came in again at 1,900. At this time a shaft is being put down on the undeveloped portion of the mine. The vein is here three feet in width and very promising. It is the general opinion that the ore of this unexplored end of the mine will prove equal in value to that extracted from the old workings. In that event the mine has still a long bright future before it. The mine is now equipped with a 40 stamp water-power mill complete in every detail. The balance sheet of the company shows not only that mining does pay, but that it pays handsomely, and that one good mine will pay for the money expended on a large number of poor mines. Up to March 1891, the Idaho had yielded \$11,265,273; of this amount \$4,845,300, has been paid to the fortunate stock-holders in dividends. Few gold mines can show a larger or more profitable record.

The Empire.

The Original Empire M. and M. Co., G. W. Starr, superintendent is located one mile southwest of Grass Valley on Ophir Hill. The mine is opened and operated by an incline shaft 2,000 feet on the vein, in depth almost equalling the Idaho. The veins are two in number distant from 100 to 150 feet from each other. The average width of the veins is 15 inches. On the veins, drifts have been run for a distance of 3,500 feet; the vein matter carries three per cent of sulphurets that run from \$40 to \$150 a ton. The quartz yields from \$15 to \$23 a ton. The mine is equipped with a fine plant, including a 40 stamp mill, that can be run by steam or water, as desired. The mill crushes an average of 75 tons a day. The mine has been in operation since 1854, and has paid in the past ten years about \$400,000 in dividends; no small degree of the success attending the operations of the mine is due to the competent and faithful services of Mr. M. Provins who has been in charge of the mill in all the mines, ups and downs since September 1, 1865, a record seldom equalled.

The North Star Mine.

Emile R. Abadie, superintendent, is two miles south of Grass Valley. The mine is equipped with one of the largest and most complete plants in the district, all operated by water-power. The mine has been operated since 1850; by the present company since 1884. During that time the company has developed the mine from the 1200 to the 2100 foot level. At the present time, the ore is from the 1800 and 1900 foot levels, with connection just made

to the 2000. The main shaft has been put down 124 feet since last fall. The vein shows an average width of 16 inches, which carries five per cent of sulphurets. These while medium in grade make up in quantity what they lack in value. The mine is one of the best in the section, as is shown by the fact that in the next few years the present company has paid \$300,000 in dividends, with a dividend of \$50,000 for April 8th.

W. Y. O. D. Mine.

C. A. Brockington is superintendent of the "Work your own Diggings" claim. This mine is down 800 feet by incline shaft, showing a vein three feet in width that carries five per cent of sulphurets that average \$200 a ton; and the vein matter delights its owners by yielding an average of \$50 a ton. The mine has been drifted on for a distance of 502 feet all in good ore.

The mine is at present equipped with a five-stamp mill; small as the crushing capacity is, the mine is paying dividends of \$1500 a month. This season a large hoisting plant and 10-stamp mill will be erected, where a steady stream of dividends of \$2500 a month can be depended upon.

The Gold Hill Mine.

Geo. Mainhart, superintendent, is equipped with a fine hoist; as soon as arrangements can be effected for water-power the mine will be started up. The mine is opened to a depth of 500 feet by shaft, with drifts run 500 feet on the vein. The vein averages three per cent in sulphurets that go \$75 to the ton, while the vein matter is reported as averaging \$10 to the ton.

Omaha and Lone Jack Con.

Geo. Mainhart is superintendent of this mine. It is opened to a depth of 800 feet on the vein by incline shaft, with drifts run up to 1700 feet in length. The mine has three ore shoots, 250 to 400 feet in length. The average width of the vein is ten inches, which is reported as carrying four per cent of sulphurets, running from \$60 to \$125 a ton, while the vein matter averages \$23 a ton. The mine is equipped with a 28-stamp mill, crushing 40 tons a day. The mine is opened by two shafts, the Omaha 800 feet and the Lone Jack 700, with hoists at both shafts and both shafts connected by drifts.

The Menlo Property.

This consists of the Wisconsin and Homeward-Bound mines, Ernest Wiltse superintendent. The Homeward-Bound may be said to be the south extension of the Omaha, and, in consequence, will in depth receive the ore shoots of that mine. The Wisconsin had been closed since 1872, the Homeward-Bound since 1881, until the present company took hold of the mines in April, 1890. The Homeward-Bound is opened by an incline shaft 360 feet deep on the vein, with drifts run 350 feet north and south, or 700 feet on the vein, showing it to be one to four feet in width, of ore that carries an average of three per cent of sulphurets that go \$80 to the ton, with the ore reported as going from \$8 to \$15 a ton. The Homeward-Bound contains three known shoots of 200, 250 and 300 feet in length, with about 100 feet between shoots.

The Wisconsin.

This mine was extensively and profitably worked in former years to a depth of 500 feet, with a record of \$20 to \$60 a ton. The present company is opening a shoot of ore not heretofore worked, and they are down over 175 feet on the vein, with drifts run 250 feet. The old shaft was on the "beel" of the north shoot, and the ore from this shoot alone extended to a depth of 500 feet. The present company is going down on the toe of the south shoot, and will run back and out all three shoots. The vein has an average width of 18 inches of ore, running three per cent in sulphurets that go from \$75 to \$100 a ton, while the quartz is reported as running from \$15 to \$30 a ton. The mine covers 3200 feet on the vein. At present it is equipped with hoists only, but the company will, in the near future, bring in water for power and erect a mill.

The Hartery Con.

S. P. Fowler is superintendent of this mine, which is opened to a depth of 600 feet by shaft, on the vein, which carries an average of three feet that runs as high as 15 per cent in sulphurets, averaging \$40 to the ton. The ore runs from \$15 to \$23. A drift has been run 600 feet on the vein, showing a shoot 300 feet long. The mine is at this time equipped with hoist alone. A mill will be erected this season. The Gold Hill, Omaha, Wisconsin, Homeward-bound and Hartery are all on Wolf creek, from Grass Valley to the Hartery, three miles south.

Rocky Bar G. M. Co.

H. Silvester is the principal owner and manager. The mine is located on New York Hill, 1½ miles south of Grass Valley. At this time it is being worked under tribute. The shaft is down 600 feet, showing a vein 12 inches in width carrying five per cent of sulphurets, that give from \$40 to \$500 a ton, while the ore has averaged \$17.50 a ton. The ore extracted at this time by the tributors goes from \$50 to \$100 a ton. There is a 10-stamp mill on the property.

The Crown Point.

A. Gauthier is superintendent and owner. The mine is just on the east edge of Grass Valley, and but a short distance from the Idaho. The working shaft is down 400 feet, with drift run 550 feet east and 280 feet west. In these workings, the vein shows an average of seven

feet of ore carrying 1½ per cent of sulphurets averaging \$100 to the ton. The vein-matter has averaged \$17 a ton. Some exceptionally rich rock has been extracted in working the mine. On the day of my visit, rock was taken out that was very liberally sprinkled with coarse gold, while Mr. Gauthier showed two pieces of rock, one of which, weighing nine pounds, had 28 ounces of gold, which at \$16 an ounce made its value \$448, or about \$50 a pound. Another piece of rock, much larger, was completely studded with fine gold. Mr. Gauthier is the inventor and patentee of a vibratory amalgamating table, which saves 15 per cent of gold over the common system. The nasal mill-plate is given a rapid shaking motion that causes the gold to settle as the pulp passes over the plate; by reason of this shaking motion, a smaller amount of water is required. The plates discharge with a very small pitch, and in consequence a much larger amount of quicksilver can be placed on the plates and the same retained.

The Coe Mine

Is owned by the Golden Queen M. Co., James Hammill superintendent. The Coe is in sight of the Crown Point, and is opened by shaft 500 feet deep on the vein, with drifts run 250 feet west and 60 feet east on the vein, showing an average width of three feet, carrying two per cent of sulphurets that go from \$100 to \$120 a ton. The average value of the ore is \$16. The company is satisfied that it has a mine and will erect a 20-stamp mill this summer.

New Eureka.

This mine, of which W. A. Weldon is superintendent, is midway between the Crown Point and Coe. The company put down a shaft 600 feet, and encountered a horse, and has been drifting west to get into ore. At the time of my visit, the face of the drift was looking very promising, with every evidence of ore ahead.

Brunswick.

E. Fitzgerald is superintendent of this mine. It is located 2½ miles southeast of Grass Valley on Union Hill. The mine is opened by incline shaft to a depth of 380 feet. On the first level a drift has been run 1000 feet on the vein. In the second 500 feet and on the third 230 feet. The average width of the vein is three feet which carries 1½ to 2 per cent of sulphurets that go \$100 to the ton. There has been no ore milled from the present development, but assays show values ranging from \$6 to \$190 a ton. The mine is equipped with a 20 stamp mill arranged for steam or water power.

The Peabody

May be said to be in Grass Valley on Gold Hill. The old shaft is down 200 feet on the vein which runs from 6 to 18 inches in width of ore that averages \$15 a ton. There is in the mine a shoot of \$25 ore called the North shoot. To tap this shoot, a fine three compartment shaft is now being put down by the superintendent, Mr. E. Tilley.

The Centennial

Is owned by H. Silvester. This property is on Boston Hill, 2½ miles southwest of Grass Valley. The mine is opened by shaft on the vein to a depth of 600 feet. The vein averages eight inches in width of ore that goes from \$40 to \$100 a ton and carries three per cent of sulphurets that run from \$150 to \$200 a ton. The mine is now under bond. The intending purchaser will proceed to equip and develop the mine and erect a mill this season.

In this connection, it may not be amiss to state that the old Watt & Riley ground, embracing a number of claims, is now under bond and will be developed this season by a strong syndicate. The properties are all on Massachusetts Hill.

Orlean G. M. Co.

This property is 1½ miles south of Grass Valley and joins the Empire on the south. It consists of six full locations, or 6000 feet on the vein. J. R. Smith is superintendent. The mine is opened by three shafts sunk on the vein to a depth of 700 feet, with drifts run on the vein for a distance of 4000 feet. The vein averages 15 inches in width, and carries five per cent of sulphurets that give \$65 to \$75 a ton, while the rock averages \$15. At this time the company is engaged in sinking a perpendicular shaft to a depth of 800 feet. On its completion and connection with the drifts, a new mill will be erected.

The Maryland.

S. P. Dorsey is superintendent. The Dorsey mine joins the famous Idaho on the east and thus claims the Eureka ledge. The location consists of 2000 feet on the vein, which is opened by shaft to a depth of 325 feet. A vein running from two to seven feet has been shown which will soon be crossed by a drift of 250 feet from the shaft. At 900 feet the shaft will cut the vein. At present all of the work is of a developing character. There has never been any doubt as to the value of this property, but it has been merely a question of development. The walls are excellent—smooth and polished like glass. In addition to Mr. Dorsey's own work, the shoot being opened by shaft on the Idaho will in time be received by the Maryland in depth and the Maryland prove a second Idaho.

The Banner Mine.

John Skewes is superintendent of this mine, which is northeast of Grass Valley six miles, on Banner mountain. The mine is opened by a tunnel 1500 feet long to the vein and shaft from the end of tunnel 400 feet deep, giving about 800 feet in depth on the vein. The vein has

been drifted on for a distance of 500 feet, showing an average width of two feet that carries five per cent of sulphurets giving \$140 to the ton, with vein matter averaging \$15 a ton. The mine is equipped with a complete ten-stamp mill, which, with all of the other improvements, has been paid for out of the returns from the ore extracted, save an assessment of \$3000. The mine is now paying dividends of \$5000 a month, with every assurance that under Mr. Skewes' practical management, they will be continued indefinitely.

Pittsburg.

The Pittsburg, Chas. Stock's superintendent, is located midway between Grass Valley and Nevada City. The property is an old million producer. In the past she has produced over a million dollars, and it is Mr. Stock's ambition to make her add several more to that number. Those who know him and the mine have no doubt of his succeeding. The mine is opened by an inclined shaft to a depth of 1000 feet, with drifts run 1000 feet on the vein, showing an average width of 12 inches of ore carrying two per cent of sulphurets that go \$60 to \$70 a ton and ore that averages \$15. The mine is opened by nine levels and is equipped with an exceptionally fine ten-stamp mill. The mine has just changed hands and is now the property of the New Pittsburg Grass Valley Gold Mining Co., Limited, which will proceed to work the mine on an extensive scale.

Chlorination Works.

The sulphurets of the section have been treated in the chlorination works of Mr. Maltman, which are midway between Grass Valley and Nevada City, and the works of Callot & Co., located one mile east of Grass Valley. Mr. Maltman's works have a capacity of three tons a day and the Callot 2½. Heretofore the sulphurets have been worked for \$20 a ton, less 10 per cent for loss, but at this time the rule is to buy outright on the assay value. For the working of the sulphurets, and the ore also, of this section and all parts of the U. S. as well, the Grass Valley Gold-Extracting Co. has erected a large plant near Grass Valley. The company owns and will operate the Pollock system of ore treatment. This is the only plant of the Pollock process in the U. S. To give the description due so important an undertaking, the full details will be found on another page of the PRESS.

Iron Works.

No small degree of profits realized in mining is due to the convenience of a near-by foundry. In this the Grass Valley mines are favored in the foundries and machine shops of Mr. Larkenna and Mr. Taylor.

The Mines of Grass Valley

Have a habit of disregarding all rules and precedents in dip and strike. Originally it was thought that those mines only, that conformed to established strike and dip could prove profitable or permanent. All this has been upset, however, until now it is simply a question of finding a fair-sized vein of quartz in the vicinity of Grass Valley and staying with it. The opening up of the number of old mines that had been abandoned as worked out, together with the development of new ore bodies, has sent Grass Valley to the front, and to-day there is the evidence on every side, that this section has a near future before her that will not only equal but excel that of any gold quartz mining district in the United States.

Nevada City.

Nevada City owed her wealth to her immense gravel deposits where gold by the hundreds of pounds—not ounces—was cleaned up at each run. When the courts closed the hydraulic mines, the people went into quartz mining in the Grass Valley section, and waited patiently for a turn in the tide. As the turn has not come, and there is no prospect of an immediate change in the tide, prospecting was begun to find gravel in the old channel that would pay to drift. The Harmony Mining Company, whose property is 1½ miles north of Nevada City, put down a shaft 330 feet, run a drift 700 feet, and cut the channel at bedrock. The company has drifted 100 feet across the channel without reaching the rim. There is from one to seven feet of pay between the bedrock and pipe clay, which averages \$1 a car. In 1860, this mine produced \$40,000.

The West Harmony joins the Harmony on the west. The owners are erecting a hoist and preparing to develop. The Cold Springs joins the Harmony on the east, but the property is idle.

The Fountain Head joins the Cold Springs on the east. The owners are erecting a hoist at this time. The channel has been prospected for a distance of two miles. While the amount extracted from the streak next to the bed-rock by drifting is less than one per cent of what could be taken out of the immense deposit (the channel is over 100 feet deep, pay all through it and miles in length), still it will put new life into Nevada City, as the extent of ground is immense. It will require a large force of miners to work it and take many years for its extraction. A snowstorm coming up prevented my visiting the mines of the Washington District, located 20 miles above Nevada City. The reports, however, are all to the effect that the mines of the section are all running to a profit. No small degree of a section's wealth is due to the hotel accommodations of a section, as capitalists dread a camp with a poor hotel. The traveling public make the National Exchange, Rector Bros. proprietors, of Nevada City, their headquarters and go back and forth to Grass

Valley by coach at a nominal charge of 25 cents for the round trip. If there is a better location for a first-class hotel, with a well-provisioned table, than Grass Valley with her 8000 inhabitants and large transit trade, I fail to know it. Success to Grass Valley!

E. H. SCHAEFFLE.

Placers of Sonora, Mexico.

NUMBER III.

EDITORS PRESS:—After demonstrating, in the manner already described, the great value of the placers of Los Llanos and Cienega, for working on a large scale by hydraulic processes, we again gave our attention to the dry methods of extracting gold from the sands and dirt, proving as near as possible the practicality of using steam as a motive power to run dry-washing machines, built on a much larger scale, than those used by the natives.

As fuel and water are abundant for steam purposes, and easily transportable to the main part of the placers, we estimated that with a good out-of-engine 8x20 inches in size, and portable, with a suitable boiler, separate, and also portable, the material could be handled in such an economical manner, as to make a handsome profit almost certain.

Our plans also encompassed the application of the power by helting to a dry-washer to be built something like one of our large threshing machines; the dirt to be fed to it by elevators, and through several sets of light steel rolls to thoroughly powder the material. The machine in other ways to run in a manner much like the method described in a previous article.

To run the dry-washer, we estimated that one cord of mesquit wood, at \$3 per cord, would be required every 24 hours for making steam, with the consumption of 1000 gallons of water in the same time, and costing say \$5 per day for its transportation. It was also figured that 15 men would be required at an average of \$1 per day each, and for wear and tear and all other expense, say \$10 per day additional, making in all an outlay of \$33 for each 24 hours.

We had no doubt but that the machine could be made to handle perfectly from 500 to 700 tons per day, and with the method of "cleaning up" the gold and black sands by means of an amalgamating pan, which we had successfully adopted in our sluicing experiments, a much better yield could be obtained than the returns by Mexican or Yaqui methods.

It will be seen that a machine working on favorable ground would clean up say \$100 to \$140 per day, or about \$60 to \$100 net profit, the work following through eight months of the year. From the great extent of the placers, it would be only a question of the number of plants like the above to bring the returns up to many thousands of dollars per month.

A dry-washing plant such as described could no doubt be obtained and placed running on the placers for about \$6000, and would easily pay for itself in a few months. The writer and his associates had about depleted the treasury of their company in paying for machinery and supplies to test the value of the grounds by wet methods, so that the six to ten thousand dollars necessary for the completion of the dry-washing scheme was not forthcoming—in fact we were placed in that not very enviable position aptly described by the Mexicans and used universally in Mexico when forced to abandon an enterprise for lack of funds, *pero falta de recursos*.

The present time is a much more favorable period for operations among these placers, as railway transportation, can be had, from San Francisco to within a few miles of the ground.

Referring again, to the placers, in a geological way, I want to say that my poor abilities, as a geologist, have not as yet, made clear to my mind, the sources of the gold. The total, or almost so, absence of gravel, among the sands, or a boulder and gravelly moraine at the foot of the placers, which might have indicated glacial movements, or the sweep of abraded streams of water, in the very olden time, was apparently not the cause of these deposits. Again it might be that many rich quartz veins underlie the placers, and whose croppings with those of other rocks, towered above the present surface; and that in time the weather-beaten ledges by sun, winds and rains, with occasional cloud bursts gradually disintegrated and abraded the different formations, freeing the gold and depositing the sands, as found at the present time. The bed-rock of the two placers as far as I observed, and that only superficially, was generally composed of a clayey conglomerate of quartz and country rock, without gravel, soft and easily picked, and contained but little gold. Many of the traditions and stories told us by the Indians and Mexicans of the bed-rock, in very favorable localities, being almost covered with gold (and which might easily have been so, had the grounds been formed by stream- or overflows of water,) we took *cum grano salis*. In fact I have found this "grain of salt" idea, to be a very convenient and economical thing to practice on, not only in Mexico, but in many other parts of the mining world.

To the west of Cienega, over the hills and ridges formed by the Teodoro mountains, lie the placers of La Calavera, named from a 30-pound lump of gold found there, which resembled in shape a human skull. From this ground the placers are very much scattered, although the gold can be traced nearly to the eastern

shore of the Gulf of California, quite 50 miles away.

Before deciding on an immediate return to California, we concluded to make a general reconnaissance of the other noted placers of Sonora. For this purpose, we hired a four-horse conveyance in Altar, with driver and guide, and procured an ample supply of arms, prospecting implements, provisions, etc., for a month's trip. Leaving Altar, we journeyed west by south, passing the ancient workings on the placers known as Sombrotita, and which we found to be several square miles in extent, shallow in depth, and hardly to be compared to Los Llanos or Cienega, although there are future favorable possibilities, provided the grounds are ever worked on a grand scale. Continuing our westerly course, we came to the once famous city of Cavora, a well-known place to many Californians, as the scene of the treacherous massacre of General Crabbie and party, by the Mexicans, in 1857.

Cavora is not noted for its placers, but rather for its vein mining of both silver and gold. It evidently had once been a city of some extent and great beauty, as an abundant supply of water made the following of all the agricultural pursuits easy and practical. Although partially in ruins at the time of our visit, much of the interesting and beautiful may still be found to employ the mind and gladden the eyes of travelers. Of the mines themselves, there is little to be said, as we found the old workings in an abandoned and dilapidated condition. At Cavora we changed our course to north by west, and started for the placers of Quitovac, located in the "dead line," in the northwestern part of the State. The town was a mass of ruins, and in possession of a tribe of Papago Indians, with whom we affiliated in a very friendly manner indeed, our guide being a noted chief of that tribe. The placers we found to trend from south to north, some 2½ miles in extent, located in a horse-shoe-shaped basin, nearly surrounded by hills, hardly reaching the dignity of mountains. From the town which is located at the opening in the basin, and at the northern part of the placer, the grounds gently rise to the south, until in a distance of about four miles, an altitude is reached of fully 600 feet, affording, in places, fine sluicing ground, provided water could be obtained. The formation is very similar to that of Cienega, with an abundance of wood and water for steam and living purposes. The water supply comes from never-failing springs, that are to be found in a low, marshy flat, one-half mile north of the village. The grounds at Quitovac prospect well, and there is no doubt in my mind but what a dry-washing plant on a large scale, put in operation there, would meet with profitable returns.

From Quitovac, we still pursued our northerly course, making for the well-known town of Sonora, just south of the boundary line of Arizona, prospecting and examining many old placers, with generally favorable results. From Sonora, we traveled easterly along the boundary line, taking in the placers of Bagnachi, in in Northeastern Sonora; then circling back westerly, through the town of Soni, making casual prospects and surveys on the route; passing through and among the placers of Las Plomosas, Las Muertas, and many others of lesser fame, finally reaching our point of commencement—Altar.

In many other parts of Sonora there are placers of considerable extent and value, notably those of San Antonio de la Huerta, El Refugio, etc., these being river mines, with boulders and gravel deposits, like many of the mining claims in California. As I can claim but little personal knowledge or experience, except among those already mentioned, I leave these placers to be described by tradition, history, or to some writer better posted than myself.

Before concluding, I desire to disclaim any intention to mislead any of our people, and more particularly miners, whose means would bebar them from working any of the placers described, except in a manner similar to that written above. "A poor man's claim" would be hard to find in Sonora. The Mexicans and Yaquis follow all kinds of mining with great intelligence and persistence, tracing veins and placers, like bloodhounds on a trail, and with the help of such poor mechanical appliances as within their reach, they leave but little to be acquired by new-comers except with the free use of capital. CHARLES MARION TYLER, M. & M. E.

THE PIONEER SMELTER.—The Salt Lake Tribune has chronicled the death of the pioneer smelter, of Utah and Nevada, Isaac Grundy, aged 80 years, who died at Minersville a few days ago. When it was learned by the Mormons, back in the fifties, that Johnston's army was coming to Utah, Brigham Young sent Grundy down to Beaver county to prepare material for leaden bullets to be hurled at the army. Grundy went to what is known as the Lincoln mine, and getting out ore, smelted it in a small furnace, and made several tons of bullion, which was sent to this city and molded into bullets. After this he was sent down into Nevada on a similar errand. Grundy is said to have been the first to make bullion in Utah.

IMPORTANT TO MINING MEN.—It will be of interest to mining companies on the Pacific Coast to learn that Commissioner Carter has given instructions to the Mineral Division of the Land Office to disregard local State laws in the matter of mineral holdings by companies incor-

porated under the laws of other States. In California and other coast States, in order that foreign mining companies might obtain mining property, a certified copy of the charter has been required to be filed. The Land Office has been following this custom and required a certified copy of their certificate. Now it is only necessary to show that it has been duly incorporated under the laws of any State.

Forestry at the World's Fair.

Not the least important of the great divisions of the World's Columbian Exposition is that devoted to Forestry. Mr. W. I. Buchanan, Chief of the Department of Agriculture, who is at present in charge of the Forestry Department, has entered actively upon the work of enlisting the various timber and lumber interests, and State Forestry Bureaus in this important feature of the Exposition. Speaking of the matter Mr. Buchanan says:

"I am very much gratified by responses received to letters sent out to State Forestry Bureaus; to the journals devoted to forestry and lumber and others interested in this subject. From the general tone of these replies I am encouraged to believe that the Forestry Exhibit will be very full and complete, and will be one of the most attractive ever shown at any Exposition.

"The importance of this department of the Exposition can scarcely be overestimated. The question of erecting a building for the forestry exhibit, through the co-operation of the various forestry interests in its construction, so as to illustrate in a unique and attractive manner all the woods of commerce in their natural and finished states, is in contemplation and is a question for future determination. The statistics of wood and timber consumption in the United States are full of meaning, and forcibly suggest that the efforts on the part of the General Government and the several States to conserve the forest supply and promote timber culture were inaugurated none too soon and cannot be prosecuted too vigorously. It is intended that the forestry display shall fully illustrate what has been accomplished in this direction, and that State Boards of Forestry will show the most desirable methods of observing Arbor Day, the benefits derived therefrom, and the progress made by them in tree culture. A comparison of notes and a general survey of the situation cannot fail to be interesting, instructive and profitable.

"In a general way, it may be said that the forestry exhibit will embrace wood in its natural state from every section of this and other countries, thus affording a most excellent opportunity for comparing the same varieties growing in different latitudes, and the climatic effect on forest growth. Worked timber in all of its many commercial forms will be shown by beautiful specimens selected from the wood-working establishments of the world, including the various ornamental woods used in furniture, veneers and interior decorations.

"The advance in the science of preparing timber in various ways to resist decay and the encroachments of animal life will be appropriately illustrated. There will be an exhibit of dye woods and barks; of lichens, mosses and ferns; of commercial gums, vegetable ivory, wood pulp, and a curious collection of seeds, and peculiarities of forest growth, such as cypress knees, hurls, etc.

"A good deal of attention will be devoted to forest botany, the distribution of forests, of genera and of species, as well as the anatomy and structure of woods, and the diseases of forest trees and timber.

"Forest management, maps, illustrations and instruments for measuring standing timber; growth of different ages and soils; graphic and other illustrations showing rate of growth; influence of various managements on tree growth; statistics of the lumber trade and of forestry; the harvesting of forest products; the turpentine and charcoal industries, will all receive proper attention.

The Stanford University.

Dr. Jordan has completed his arrangements for the appointment of the Faculty for the Stanford University, and has made the following names public:

Dr. Andrew White, ex-president of Cornell University, to be non-resident professor of history.

E. Stanford, Lake Forest University, associate professor of physics.

Horace B. Gale, Washington University, St. Louis, professor of mechanical engineering.

Professor Joseph Swain, Indiana University, associate professor of mathematics.

Douglas H. Campbell, Indiana University, associate professor of botany.

BLUE LAKES.—Professor Frank Soule has recently returned from an inspection of the water rights and works of the Blue Lakes Water Company in Amador county. He says that at the point in the Mokelumne river where the inlet of the company is established, the stream is a fine, large, wide river of the purest water, fresh from the melting snows of the Sierras. By its rights, the company practically holds control of the stream, which in volume would easily apply the whole of San Francisco, Oakland, Stockton and Sacramento combined. Some of the water is carried along a canal and flows to numerous mines and mills 30 to 50 miles below.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Alpine.

TO BE REOPENED.—Genoa Courier, April 15: Despite the fact that Alpine has been on the down grade, the prospect before the county is a very bright one. There is every indication that several mines will be reopened the coming summer and a general awakening of business is looked for. The Good Hope mine, about three miles above Markleeville, near the river and formerly worked by Will and Frank Musser and Charlie Grover, will be reopened shortly by a man from California. It is stated that the Morning Star or Stella mine, the Colorado No. 2 and the Isabella Tunnel Co. may all resume work in charge of new hands this summer.

Amador.

HARDENBURGH.—Ledger, April 18: The 10-stamp mill of this mine at Middle Bar is nearly completed. W. White, the contractor, expects to get through with the carpenter work next week. The concentrators are on the ground. They are of the Woodward make, which are said to give even better results than the Frue, besides requiring less care in handling them. The course of the ditch that supplies the water has been somewhat changed. Instead of going close to the shaft of the Mammoth mine, it has been carried round the hill, thereby avoiding all danger of seepage into the Mammoth works. At the mine they are taking out some fine-looking ore, which, judging from appearances, ought to pay well. Inside of a month the mill will probably get to work, and set all doubts at rest as to the paying quality of the rock.

NORTH STAR.—The bond of this property expires in June. After the expenditure of nearly \$50,000 in search of a mine, the company is loath to abandon it without further exploration. The discovery of bunches of rich quartz creates the impression that a definite ledge must exist within the limits of the claim. It is likely that an extension of the bond will be asked for, and in the event of such extension being granted, the company will be reorganized, and the ground explored to greater depth.

KENNEDY.—The north shaft has reached a depth of 1350 feet—100 feet deeper than the main shaft. After opening stations at this level, sinking will be commenced on the south shaft, which will also be carried to the same level as the other. The water which was found to be so troublesome in sinking the north shaft, ceased below the 1250 level, and the last 100 feet is comparatively dry. A tank has been put in below the water line, which catches most of the water, and which saves 100 feet of hoisting. The mine continues to surrender liberally in gold, holding the place of the largest gold-producer in the county.

SOUTH EUREKA.—After protracted negotiations the promoters of this venture have at last got the property in shape for the commencement of work. The mine is on Tanner hill, above Sutter creek, and lies on a direct line between the old Eureka and the Oneida mines. It is conceded on all sides to be a very likely location for the opening up of a valuable mine. Arrangements have been made with capitalists below for the necessary funds, in monthly installments, to give the ground a thorough prospecting. It is virgin ground; not a single shaft exists on it. As the entire tract is covered with a bed of lava, supposed to be 100 feet thick, it is a difficult matter to determine the best place to sink the prospect shaft. The apparent line of the lode as indicated by the old mines at either end will probably decide this to a great extent. Surveyors are at work, and in a couple of weeks the era of active mining will be inaugurated upon this promising property.

MISCELLANEOUS.—Forty stamps of the Pacific mill were started this week on a small vein of good ore encountered in the Pacific mine. It is reported that Ballard and Martin, the owners of the New London mine, are negotiating for the purchase of the Alpine mine at Plymouth.

SUTTER CREEK.—Cor. Amador Ledger, April 18: Mining has taken a slight tumble since my last. The North Star Co. have become discouraged and called a halt in the operations. One meeting of the stockholders has been held to decide what should be done, but as the views expressed differed so widely, no conclusion was reached. Some were in favor of coming up to the 600-foot level, and extending the drifts there. It is more probable, if the work is continued at all, that they will conclude to sink another 200 feet, which is generally looked upon as the wisest plan. Work may be abandoned altogether, as some stockholders are not disposed to keep up assessments any longer. It is stated, however, that several moneyed men stand ready to take all the stock that may be surrendered, and continue the work for some time to come. Another meeting will be held shortly, when some definite understanding will be reached. Operations have also come to a sudden standstill at the Lincoln mine. Owing to the late rains, the tunnels, not being sufficiently timbered, have caved in, and as the ore is of low grade, the work of clearing out and retimbering is discouraging. In all probability the lessees will drop the undertaking entirely. They have taken up the plates in the mill, and a thorough clean-up will be made. The Lincoln is regarded as the best mine in Sutter Creek, and all it needs is a strong company to put the shaft in good order, make another sinking, and develop the property in a workmanlike manner. This can never be done by local operators, as it involves too great an outlay. Work at the Mahoney mill is progressing favorably. The tail race has been torn up, and will be replaced with something substantial. The mill has been idle so long that a complete overhauling is necessary before the stamps can be put in motion. Superintendent Tihthets reports on the Belmont mine as follows: The work of reopening the tunnel has been pushed ahead with night and day shifts since February 6, and now the breast of ore has been reached, fully 20 feet in width, and the company have started their 10-stamp mill, working from 15 to 20 tons per day, with good results. The height of this ore breast above the tunnel is between 50 and 60 feet, which has been well prospected by shafts sunk from the surface at intervals north 450 feet, showing a continuous body of ore the entire length. Upward of

30,000 tons of ore is estimated in this body from surface to tunnel, which will now be mined and milled. Work on a level 60 feet below the tunnel is being pushed ahead on the vein, and is in about the same distance north as the tunnel above. The face of this drift is in ore its full width. No crosscutting has yet been done to show the width of the vein at this depth. Ore at this point carries from two to three per cent of sulphurets, and prospects in free gold. The mill is run by water-power, is in good repair, and doing first-class work.

Calaveras.

GLENCoe.—Cor. Chronicle, April 18: The Columbia mine (better known as the Jones mine) has begun operations again and it is hoped that they may meet with success. The mine is owned by Jones & Garland, and is located between Glencoe and Railroad Flat. The small machinery used in operating the mine formerly, has been removed and some larger machinery substituted. A contract has been let to sink fifty feet, and after this has been completed, levels will be run both ways. The mine shows a well developed vein with regular walls, and plenty of the yellow metal. James Enright, the owner of the Bald Eagle mine at Railroad Flat, has purchased eight stamps of the twenty-stamp mill belonging to Mr. Garland, Glencoe's former mining expert, which he (Enright) intends removing to his mine at Railroad Flat. We hope that Railroad's popular first-base man may meet with success, not as a ball player but in his mining interests. F. J. Horswill, who formerly operated on the Norwich mine here, has begun taking down the machinery which he intends removing to Mokelumne Hill.

THE CHILO QUARTZ MINE.—Calaveras Prospect, April 18: During the week we were informed that Hiram Tyer and Tom Stapp, who have been prospecting the Chilo quartz mine, about one mile south of the Calaveras river near J. G. Vote's ranch, had discovered some very rich rock. The owners of this mine have been prospecting for some time. A shaft has been sunk over 75 feet deep, and a few days ago while some work was being done on the surface a quantity of very rich rock was found which was traced along the lead for some distance. The owners of the claim intend to have several tons of ore sent to Selby & Co., to be tested.

TO BE WORKED.—Angels Echo, April 16: There will be considerable work done in this locality during the coming summer. Mining property that has been lying idle for months past will be worked and there promises to be a general revival of mining operations throughout the whole district.

MILL.—Preparations are making for the erection of a 20-stamp mill on the Hallock mine, formerly the Tiberghen mine, situated about a mile west of Angels. Tulloch's concentrators will be used in the mill.

UTICA.—Everything is running in excellent order at the Utica mine, and the 60-stamp mill is kept employed in crushing ore from the stopes of the north and south shafts. The Utica is one of the best mines in the State, and certainly the leading mine of this locality. Nowhere in the State is there another such a vein of ore. The ledge in the Utica averages 60 feet in width, and it is not of the bunch formation, but a solid vein of ore that extends downward and gives every indication of lasting for years to come. A contract has been accepted to sink the south shaft of the Utica 230 feet deeper, which will make the mine 800 feet deep when completed, and the deepest mine in this part of the country. The Utica Mining Co.'s chlorine works, situated in the eastern part of town, are kept in constant operation.

Inyo.

MINING STRIKE.—Index, April 15: Recent developments in the Hirsh mine, Russ district, owned by Nathan Rhine, are of the most encouraging character. The ledge is now four feet in width, with two feet of cube galena averaging 90 ozs. of silver per ton. The rest is made up of a good proportion of honey-comb quartz which prospects well in free gold. About 15 tons of ore is now out and a shipment will be made at an early day. This new strike in the old mine will give an impetus to mining operations all along the Inyo range. Those mountains are full of rich minerals.

Shasta.

UNCLE SAM.—Shasta County Democrat, April 14: It is reported in town that the Uncle Sam mining company have at last cut the ledge in the lower tunnel they have been running for the past seven or eight months, which will give 600 feet perpendicular, of stopping ground, or 400 feet from the level of the old tunnel. The vein, when encountered by the new tunnel is strong eight feet in width, and the ore is said to be high grade. This establishes the permanency of the pay chutes of this camp.

Nevada.

BRUNSWICK CON. M. CO.—Grass Valley Union, April 18: Supt. Fitzgerald's last report to the home office at New York has this to say of the present appearance of the Brunswick Con. mine of this district: "Mine looking well; ledge of same character of quartz as reported before. During past week have made 56 feet of ground, 26 feet in east drift and 30 on west drift. Gained seven feet more of ground by contract than by day work, and at less expense. Have placed in mine a two-foot Pelton wheel and a two-foot fan, which will give all the air wanted and enable us to sink shaft 200 feet deeper. The drifts are being run steadily on full 24 hours' work, and are getting near the ground I expect so much from. Everything looks promising and there is every indication of better prospects as stringers of ore are coming in on hanging wall and crossing the drift. It is a good sign for more quartz. Am taking out quartz and it all looks like pay."

CHAMPION MINE.—The annual meeting of the Champion M. Co., Nevada district, was held on the 14th inst. The official reports were favorable as to the operations of the company. Dividends to the amount of \$25,000 had been paid during the past year, besides \$11,000 for the purchase of the Merri-field property. A dividend of 10 cents per share was declared, payable on the 25th inst.

IDAHO MINE.—Grass Valley Union, April 14: A large station has been cut on the No. 18 level of the Idaho mine, where the fissure is wide, and on the footwall a vein of quartz is exposed that shows liberally in free gold. As this is below the main ore shoot found in the levels above it may prove a very valuable find. The new hoisting works on the eastern end of the location is approaching completion, and the old prospect shaft over which the works are built has been strongly timbered, with a view of

sinking on the lode, which is between two and three feet in size at that point. It is not unlikely that a new pay shoot will be found in that portion of the mine.

THE NORTH BANNER CO. has it in contemplation to add ten additional stamps to its present ten-stamp mill, to increase its crushing capacity, as the mine can now produce more ore than the mill is capable of crushing.

Sierra.

GOOD PAY GRAVEL.—Mt. Messenger, April 18: The Extension Co. raised its second shaft at a distance of 100 feet beyond the shaft where gravel was found at height of 60 feet, and again found gravel, this time after raising 26 feet. Meikle got out and washed four carloads Thursday, in a small prospect dump which he had rigged up for the occasion, and found that it paid \$3 a load. The bedrock at this last raise lies nearly horizontal, and that, in connection with the other facts that the wash is heavy and the pay good, warrants the assumption that the bottom of the channel has been reached. It will be some time before much of a force can be put on, as a large amount of preliminary work must necessarily be done in the way of building dumps and opening breasts, etc.

POKER FLAT.—Cor. Mt. Messenger, April 18: Bunker Hill is employing five men at present. A big future is predicted for this mine. The Liberator mine, situated at Deadwood, is to be started up soon by Sam Miller. The Sunnyside tunnel is in 600 feet in soft, picking bedrock. The indications are that pay is not far off. A rich strike made a short time since, proves that all the mines are not worked out yet. P. O'Donnell, J. Clark and J. Frazer, while out prospecting a few days ago, found a rich deposit which they firmly believe is a break-out of the old Howland Flat lead. They found one nugget weighing ten ounces, besides several others weighing from \$5 to \$50. The finders are jubilant over their good fortune. T. C. Corlett has been sinking an incline on his property, and has found a very rich prospect. Some of the gravel will prospect \$100 to the carload. The Forest Queen Co. is running for the same lead. The tunnel is in about 400 feet, A. Brown and Wm. Jones are working on their claim adjoining the Forest Queen. They are taking out good pay gravel.

Tuolumne.

TUOLUMNE RIVER QUARTZ.—Independent, April 18: Work is commencing on the Tuolumne River Quartz Co.'s mine, near Groveland. The mine is situated on the south bank of the Tuolumne river, near Groveland, about fifteen miles from Sonora. The company owning the property was incorporated March 18, 1891, with a capital stock of \$120,000, in 120,000 shares, at \$1 each. A. B. Cruickshank is President, and Jahez Howes, Secretary, with principal office in S. F. The property consists of a group of twelve gold quartz mines and a mill-site. There has been expended on the Mary Ellen mine (one of the group) and mill-site, \$35,000 in improvements and developments. The Mary Ellen mine and mill-site is held under U. S. patent, and the other under the mineral laws, and subject to patent at any time. The property has been favorably reported on by eminent mining experts and engineers. The mines are very favorably situated on the side of a mountain, thus doing away with expensive hoisting and pumping works, all the ore being run through tunnels; this together with the fact that free water for power can be obtained the year round, enables the ore to be worked very cheap. All the ore so far crushed has realized \$30 per ton, by steam power; but, with water power, the ore can be worked much cheaper. The mine is already equipped with a new 10-stamp mill and all buildings and improvements. The other mines will be developed by tunnels, in bringing in water by ditch and flumes, and other appliances and additions to mill and plant. A. A. Moore, of Sonora, has the contract for the pipe work, and matters will be pushed along the whole line of development as fast as possible.

NEW ALBANY.—Sonora Democrat, 18: The water is being rapidly moved from the 800-foot main working shaft of the New Albany mine, preparatory to mining and milling operations. The new hoisting gear works well. Parties in San Francisco are looking to the Pino Blanco and Hancock mines situated near the Badger mine. The titles having been examined and found satisfactory by Mr. Louis Blanding, the parties will soon visit the mines for inspection and negotiation. Work of development and test has been started on the Alameda mine, situated on the mother lode, by the San Francisco parties having a 90 days bond on it. Mr. Harman of this county is owner. The work is in charge of Mr. Frank McCann. The past record of the mine speaks well for a lasting and profitable property. Work on the Page mine has begun to place it in operating condition by the parties who lately acquired the property. New buildings and mill will be erected on the mine. Drifting is now being done on the 200-foot level of the Badger mine. The ore coming out from the vein, which is four feet wide, is of good paying quality. A shipment of ore will be made at an early day to the Sonora Reduction Works to determine its value in free gold, the percentage of sulphurets in the ore and their value per ton. The parties having a bond on this mine are entirely satisfied with the property. The mine is situated about three miles to the west of the Mother Lode.

Yuba.

SMARTSVILLE.—Grass Valley Union, April 25: A new mining incorporation has been organized under the name of the Syndicate Mining and Development Company, to operate on the Blue Lead at Smartsville. This company will open the ground on the south end of the Blue Lead through a tunnel on what has been known as the "Dunn ground," and will work back into the Mooney Flat ridge. It is expected that pay dirt will be struck in 30 days after commencing work. The company will have about 100 men at work in a short time. The new company will have a location covering one-third of the land, extending from the lower end through to Mooney Flat on the north end, which is being worked by the Ayers Co., and the striking of pay gravel will demonstrate that the lead is continuous for a distance of between two and three miles.

NEVADA

Washoe District.

CONS. CAL. AND VA. MINE.—Virginia Chronicle, April 18: There has been extracted from all parts

of the mine during the week 1482 tons of ore, which was shipped to the Eureka mill. The average assay value of all of the ore worked at that mill during the week (1575 tons) was \$33.80 per ton. Bullion now on hand in our assay office, assay value, about \$31,000.

OPHIR.—The upraise started in the drift run south from the drift run west from the winze, 122 feet below the sill floor of the 1300 level has been carried up 7 feet; total length, 23 feet; and from this opening some ore has been extracted and stored in the mine, the average assay value of which is \$23.50 per ton.

MEXICAN.—The east crosscut, No. 1, started from the main north lateral drift at a point opposite the west crosscut, No. 1, has been extended 30 feet; total length, 661 feet; in soft porphyry formation showing fine lines of quartz.

UNION CON.—East crosscut No. 2 on the 1465 level, started from the north lateral drift at a point 200 feet north from the south boundary line of the mine, has been extended 25 feet; total length, 819 feet; continuing in a hard porphyry formation.

ALTA.—Building a new tank at the mine and overhauling the mill preparatory to the resumption of mining and milling.

YELLOW JACKET.—The usual prospecting work is being done throughout the mine.

JUSTICE.—The north drift on the 822 level advanced 26 feet since last report, and is now out a total distance of 530 feet; the face is in a mixture of clay and quartz. The south upraise on the 490 level was sunk five feet during the week, and has now a total depth of 45 feet; the bottom is in fair milling ore.

OCCIDENTAL.—Extracting ore of fair grade from the 350, 400 and 450 levels. The south drift from No. 1 winze, 600 level, is in 81 feet, the face showing pay ore. The north drift from No. 2 winze, 659 level, is in 274 feet; the face is in quartz and porphyry. Have started a south drift from No. 1 winze, 750 level, in quartz showing some value.

KENTUCK CON.—The south drift from the 1000 raise, east ledge, was advanced 11 feet during the week, and is now out 37 feet; face in low-grade quartz. Have started to open the third set above the track floor in the east crosscut from the north lateral drift on this level. The top is in low-grade quartz on the average, but showing some spots of ore.

BELCHER.—The south drift from No. 2, east crosscut, 300 level, is out a total distance of 174 feet; face in low-grade quartz. West crosscut No. 3, 300 level, has been advanced 34 feet since last report, making its total length 310 feet; face in vein material composed of porphyry, clay, low-grade quartz. The east crosscut on the 1500 level is out 49 feet; face is in hard porphyry.

CHALLENGE AND CONFIDENCE.—The joint Confidence and Challenge west crosscut from the north drift on the 300 level is out 68 feet, having been advanced 6 feet this week. The joint Confidence and Challenge east crosscut from the north drift on the 1100 level, is out 55 feet, 20 feet having been added. The face is in porphyry. The joint Yellow Jacket, Confidence and Challenge north drift on the 100 level is in 694 feet, 33 feet having been made during the week. The face shows quartz having no value.

CON. IMPERIAL.—We are still following up and taking out small streaks of ore from the upper levels and prospecting in and around the old stopes, where we found some fillings and bunches of ore of fair grade, which is shipped to the Vivian mill for reduction.

CROWN POINT.—The south drift on the 300 level is out a total distance of 124 feet, having been advanced 26 feet during the week. At this point it was stopped and a raise started on a streak uncovered in the drift 40 feet south of the stope. The west crosscut, 1000 level, has been extended 12 feet, making its total length 62 feet. It will be continued a short distance farther in order to determine positively whether or not the material in the face is the foot-wall.

ENCHEQUER.—East crosscut on the north line, 600 level, is out 177 feet; face in porphyry.

ALPHA.—The winze 80 feet north of the shaft, 500 level, is down 95 feet; the bottom in quartz yielding low assays.

CHOLLAR.—Northwest crosscut, 60 feet above the 550 level, is in 41 feet, the face in quartz yielding low assays. West crosscut 50 feet south of the north line, 1400 level, is out 21 feet; face in clay and quartz. Joint east crosscut on the north line, 1400 level, is out 65 feet; face in porphyry and streaks of quartz. Milled 542 tons of ore worth \$10.02 a ton, as per battery assays.

POTOSI.—The 1100 level south drift is in south of Chollar incline 57 feet, face in porphyry. The south drift from the winze station, 1300 level, is in 55 feet, face in porphyry and streaks of quartz giving low assays. The winze is down 30 feet below the 1400 level; the bottom is in clay and quartz.

UTAH.—On the 725 level south drift from the main west drift, 140 feet from the shaft station, the incline raise has been carried up 59 feet; total height on slope, 98 feet. The raise is continued in quartz and porphyry, assaying low in the precious metals.

ANDES.—During the week repairs to the north drift on the 420 level were completed and an east crosscut started from the drift. The crosscut has been advanced eight feet; formation principally porphyry. The east crosscut from the south lateral drift on the 220 level has been advanced 16 feet; face in a formation of vein principally quartz.

SEG. BELCHER.—On the 600 level the east crosscut from the south lateral drift is now out a total distance of 248 feet, having been advanced 17 feet during the week. The face is in hard porphyry.

SIERRA NEVADA.—630 level—North lateral drift from west crosscut No. 1, is in 69 feet. West crosscut No. 1 on the same level was advanced the past week 25 feet; total distance, 231 feet, bringing the crosscut 55 feet in the west country formation.

GOULD & CURRY.—200 level: Extracted from old stopes during the week 91 cars of ore. Sent to the Nevada mill 518 tons of ore; average battery assay, \$23.68.

BEST & BELCHER.—1000 level: Have repaired 125 feet of north drift. 1100 level: Northeast drift has been advanced 20 feet through hard porphyry mixed with seams of clay and quartz; total length, 79 feet. 1200 level: All work for the week has been on repairs.

HALE AND NORCROSS.—On the 1100 level of Norcross No. 4 west crosscut near our north boundary was advanced 25 feet; making its total length 195

feet; face in quartz and porphyry. No. 5 east crosscut started on our south boundary was advanced 30 feet; total length, 65 feet; face in porphyry and quartz. The winze started from the end of No. 3 east crosscut, 80 feet south of our north boundary, is down 40 feet. The bottom is nearly all in ore of excellent quality. The main incline is repairing and retimbering 135 feet below the 1400 level station.

SAVAGE.—We have hoisted 773 cars of ore from the 500, 700, 800, 900 and 1100 levels and from the intermediate drifts north and south from the winze below the 1300 level. Shipped to the Mexican mill 557 tons and milled 580 tons; average battery assay, \$17.59. We have bullion on hand amounting to \$10,537.80. The upraise from the 300 level is advanced 154 feet and continues in low-grade ore. On the 950 level the south drift from the station was advanced 33 feet; the face in low-grade ore. On the 1100 level the north prospecting drift from Hale & Norcross side was advanced 20 feet, the face showing stringers of fair-grade ore. The face of east crosscut No. 100 the 1400 level is in quartz and porphyry.

Eagle District.

PROSPECTING.—Salt Lake Tribune, April 17: John Tippet, recorder of Eagle mining district to the Deep Creek country, arrived in the city yesterday. This district is some 25 or 30 miles southwest of Deep Creek station, hence in White Pine Co., Nevada, and embraces part of Eagle range, or Kern mountains. Mr. Tippet has lived there the past seven years, all of which time he has been prospecting, working on his numerous claims and taking out enough ore to keep him and what help he hired. He has shipped mostly from his Harrison mine, located in granite, having a vein three to six feet wide and producing ore that went from 300 to 500 ounces silver, with very little lead or copper. He ran a tunnel on this vein 100 feet, 10 ore all the way except some 10 or 15 feet. On his Anoa he has a shaft down 60 feet, and has taken 100 tons of ore out of the mine which ran from 500 to 600 ounces silver. The vein is 5/8 to 1 foot wide, one-half being rich while the other is second-class, but with a mill would pay well to work. It is chloride ore and hence cannot be concentrated without great loss. The Paymaster produces ore up to 150 ounces silver, 25 per cent lead and carries some iron. This vein is 10 to 12 feet wide and has been opened but little. The Exchange is a new strike of three-foot ore which runs well in silver and some copper. Then there is the Bell which samples 45 ounces silver, but few persons are in Eagle as yet, probably 20 in all, who are prospecting and working on their claims. The Mint is another of Mr. Tippet's properties, 14 miles west of Eagle, in Pleasant valley, and it samples 60 to 150 ounces silver.

Pioche District.

SMELTER.—Record, April 16: With the smelter already in operation, and the two stacks to course of erection, we may look for more lively times the coming summer than has been experienced for some years past. Work at the new smelters at Clafin is being pushed with considerable vim and the new stacks will soon be up. The coming summer will see quite a settlement spring up in that locality.

Tuscarora District.

NAVAJO.—Times-Review, April 16: Stopes on the 350 level are improving, and though the vein is small the ore is of an unusually high grade.

BELLE ISLE.—The drifts from the intermediate crosscut from No. 1 chute, 350-foot level, have been extended 20 feet, still showing some good ore in the face, though not as much as at first. West crosscut from No. 2 chute, same level, extended 16 feet, the face is now entering vein matter.

COMMONWEALTH.—Fourth level: East crosscut has been extended 23 feet in porphyry. North drift from east crosscut advanced 24 feet, face showing some low-grade ore. South drift from same point extended 20 feet in the vein, a large flow of water from both drifts. North drift from west crosscut advanced 14 feet, spar and clay in the face, giving low assays. South drift from same crosscut extended 6 feet, following a small stratum of ore.

NORTH COMMONWEALTH.—First level: Started raise No. 3 from south drift, up 30 feet, cut the vein 65 feet south of the stopes, exposing good ore. Ore extracted during the week was 30 cars first class, average assay \$296 per ton, and 45 cars second class, assay from car sample \$20.70 per ton.

NORTH BELLE ISLE.—East crosscut from north drift, 400-foot level, extended 16 feet; the face shows three feet of vein, 10 inches of it being high-grade ore. Stopes from the 500 level are not looking as well. Have broken nine cars of first class and 73 cars of second-class ore. West intermediate crosscut from No. 3 chute has been advanced 12 feet into the hanging-wall. North intermediate drift from No. 4 chute, 600-foot level, extended 14 feet.

ARIZONA.

STERLING.—Tombstone Prospector, April 17: J. T. Fisher of the Sterling Silver Co. has gone east to confer with his company regarding future operations. He is confident of finding big bodies of ore below water in the Vizina and is also confident of a speedy settlement of some plan to drain the mines. J. P. McAllister maintains that such vast improvements have been made in pumping machinery in the past eight years that \$75,000 will put in an adequate plant to drain the Tombstone mines and keep the water out. Mr. McAllister has made a study of machinery all his life and speaks from practical knowledge. When the Grand Central pumps went up in smoke it was said they could not be replaced for less than a quarter-million of dollars, but that was seven years ago. The mill at Tevis Camp is being worked again and the successful production of high-grade concentrates is again in active operation. This process, it should be remembered, is the dry concentration or Graeger process. The weather being dry no trouble is experienced and dryers will be ready to use when the rainy or moist months come around. Mr. Duncan, who furnished the capital to develop these properties, is strong in his praise of the process of dry concentration.

EMPIRE.—Moberg Miner, April 18: The Empire mine has another large shipment of ore on the dump and vast reserves in the mine, and more being constantly added. Over 100 feet of water has been pumped from the C. O. D. shaft, and it is expected work on the upper levels can be commenced in a short time. Joe Waggoner and Ike Conkey are working on the Illinois mine at Cloride and are taking out some fine ore. The Illinois is the first

south extension of the old Juno mine. The New London mine has been leased to parties who contemplate going to work on it immediately. The New London has heretofore produced hundreds of tons of high-grade lead ore. Shaw & Marshall have leased a portion of the Nighthawk dumps and are getting some good ore. The remainder has been leased or purchased by the Empire mill and the most of it will be run over the Free vanners of that mill. The two winzes being sunk from the 300-foot level of the Cupel mine are in ore of exceeding richness. Owing to an accident to the pump, sinking has been discontinued on the main shaft until a duplicate of the main parts can be obtained. John Barry was in town Monday and Tuesday. He ordered considerable timber and mining supplies for the Sunlight mine. The water has all been pumped from the mine and sinking will be commenced in a few days.

DAKOTA.

A NEW REDUCING SYSTEM.—Deadwood Pioneer, April 14: Yesterday Wells, Fargo & Co. received a large tin pot, consigned to N. L. Anderson, which looked as though it was intended to boil soup in, but which is, in reality, a miniature reduction works, which may develop important results in the way of reducing refractory ores in the Hills. The pot is a reproduction, on a small scale, of the system that has been in use in Montana for some years, and if it will work on the ores in Ruby Basin and Bald Mountain, a large plant will be established in this vicinity. The works, as in operation in Montana, consist of an iron cylinder arranged with four shelves. The charge of ore, consisting of five tons, is dumped, uncrushed, on the first shelf, and subjected to a roasting by means of jets of burning petroleum, while, at the same time, water is sprayed over the charge of ore. As the roasting progresses, the ore is dumped from one shelf to another, until the roasting is completed. Then the charge is placed in an ordinary miller, with a quicksilver plate in the bottom, and the charge passed over it. The gold and silver amalgamates with the quicksilver and pulp is washed off. It is said that a 30-ton plant can be erected for \$2000, and the cost of reducing the ore is \$1.70 per ton. A carload of Ruby Basin ore has already been shipped to Montana for an experimental run and should this system prove satisfactory, large reduction works of this kind will immediately be erected in Deadwood or closely adjoining the city.

SQUAW CREEK DISCOVERIES.—Deadwood Pioneer, April 15: The late strike of carbonate of lead ore on Squaw creek, a stream that runs through the country that lies between the Etta tin mine, and Hermosa, created considerable excitement, and as soon as it became known 150 or 200 men rushed to the scene and soon had all the ground in the neighborhood located. Outside of the first discovery very little similar ore has as yet been found. It is the opinion of some of those who have visited the place that it probably came from a chimney. The ore runs pretty high in lead, and fair in silver. It is to be hoped that on some of the other claims the same kind of ore will be found. If there is one thing more than another that is wanted in this country, it is lead.

IDAHO.

DELAMAR.—Idaho Statesman, April 15: Geo. Drake, one of the contractors on the lower tunnel, says they have been making excellent progress with their work, having run 170 feet during the past month. They are still some distance from the main ledge, but have cut through several small ledges of good quality. On the 4th inst, the DeLamar property passed from the hands of Capt. DeLamar into the control of the DeLamar Gold Mining Co., limited, the final transfer having been made on that day. Mr. Werteweller arrived on the 2d, and represented the company in the transaction. Mr. Bratnaber also came in on the 4th, and has assumed charge of the property for the time at least. Mr. Plummer is expected here about the last of the month, when, it is rumored, he will be installed as general manager. On the 4th and 5th, the stamps were hung up and the final cleanup for Capt. DeLamar was made, the net results being something over \$100,000. The mill was immediately started up again crushing ore for the new company, and is already pounding out dividends for the stockholders. On the 4th and 5th a complete inventory of all the property belonging to the company was taken. No changes of importance have followed the transfer of the property, and none are likely to occur until the general management has had time to digest their plans and settle on a line of procedure.

THE MAMMOTH MILL.—Wardner News, April 11: The old idea of being obliged to visit some other place when in search of news from home has been amply exemplified during the past month by the accounts published in the numberless newspapers both in and out of the State regarding the starting of the new concentrating mill of the Bunker Hill & Sullivan mining company. The Spokane papers have recorded it as being in full blast for a month, while other journals nearer home have had the mammoth works in operation for nearly two weeks. The fact is one half of the plant was set in motion during the week to test the machinery which was found to work like a charm and the entire works will commence permanent operations about next Monday. When all the necessary arrangements for starting have been completed, and the largest mill of its kind in America begins to concentrate, the News will give an account of its workings.

THE ARGENTINE MINE.—O. M. Lonsdale one of the owners of the Argentine mine located near Osburn, said on Wednesday last when interviewed by a Review reporter in Spokane that the mine, which has been shut down for two years because of a misunderstanding of the stockholders, will be opened up in about six weeks. The Argentine is one of the mines in the Coeur d'Alenes that has been well developed, but the length of time that it lay idle put it behind the others in production of ore. The work of completing a 400-foot tramway that was destroyed by a snowslide this winter has just been done, and the mine will begin operations with a force of half a hundred men. It is a dry ore mine, the rock running 60 ounces in silver and about \$6 in gold. The Last Chance Mining Co. have just added to their mill one of Clark's

improved slime tables. This new improvement on the old method is the invention of Edward W. Clark of Butte, Montana, who is now here superintending the putting of his table in place.

ATLANTA MINES.—Gilmore Bulletin April 18: Again the report comes to us that the sale of a group of Atlanta mines has been perfected by Judge V. S. Anderson, the purchasers being a London syndicate and the price \$3,500,000. These claims were owned by 25 or 30 men, mostly residents of Atlanta, Rocky Bar and Boise City, and we predict that each locality will feel beneficial effects when these "old boys" receive their share of the English coin. Judge Anderson departed from New York for London on the 15th instant to close the bargain, and Lawyer Sam McCarty informs us by telephone that all necessary papers are now on file for record in the County Recorder's office.

MONTANA.

GRANITE MOUNTAIN OUTPUT.—Mining Journal, April 15: The output of the Granite Mountain Co. for the past week aggregates 44 bars, containing 66,000 ounces silver and 158.4 ounces gold.

THE EXEMPTION SUSPENDS.—Pending the raising of a fund sufficient to sink the shaft 140 feet deeper, work on the Exemption at Butte has been suspended. At a depth of 60 feet, which is the point reached before the work was discontinued, the ore body is said to show 3 1/2 feet in width.

A SEVEN THOUSAND DOLLAR BONUS.—It is reliably stated that Humphrey & Richardson, who recently bonded the Carter, at Barker, for a continuing consideration of \$15,000, have transferred their claim to John Sinclair and others of Great Falls for \$22,000, receiving, therefore, a bonus of \$7000. The Carter is owned by Ed Zingler and John Clifton and bids fair to become a bonanza. It is an extension of the Paragon.

WILL ACTIVELY DEVELOP.—The El Dorado Co., operating just west of the O. R. & N., in Missoula county, has determined to commence active development of its property at once. From the surface showing, as well as its environments, the claim is regarded as of unusual promise. It carries two leads which come together and cross within its lines. One of these, the King & Queen vein, carries grey copper and runs northeast and southwest. The other, the Keystone, carries steel galena, and runs east and west. The King and Queen to the west has a shaft 300 feet deep, with eight feet of solid ore at the 150-foot level and 14 feet at the 300.

THE HELENA SMELTER.—Mining Review, April 17: As an additional evidence of the flourishing condition of the mining industry in Montana, we are informed that the sum of \$100,000 will be spent this spring in constructing additions to the Helena smelter, which has already cost a half million. This concern is now running to its full capacity, but the ore resources from which it has to draw being so numerous and the returns so great, it has been decided to enlarge the plant at once. This addition will make the Helena smelter one of the most complete in the world.

CASTLE MINING DISTRICT.—Inter-Mountain, April 16: E. P. Snydam, the energetic mining man of Castle, brought in a box of samples to-day from a group of mines in which he is interested. They are located in the Four mile camp of the Castle district and include the Granite Mountain, Myrtle and other well-known claims. The ore is on exhibition at the office of W. D. Fenner & Co. Mr. Snydam recently made a map of the mining claims in the Castle district with a statement of the development and ore in sight which is very valuable. He says the mining men of Smith's camp contemplate building a smelter for treating the ores of the Judge, Bondholder, Legal Tender and Alice mines. A custom smelter, he says, would do a great business. The Cumberland smelter is being rapidly built and everything about Castle has the appearance of life and activity. About 1,500 people are now around the camp.

OREGON.

PLACERS.—Bedrock Democrat, April 18: More than the usual activity in mining circles is manifest this spring and while the weather has not been so favorable for the placer miner, there seems to be no reason for uneasiness. The days and nights have been cold and the snow is melting slowly. But, then, it is a backward spring and judging by the experience of the past all things will yet turn out favorable. A few days of sunshine will start the flow of water from the mountains and as there is a large quantity of snow banked up in the ravines and gulches the water season promises to be a lengthy one. From all the different camps throughout Baker and Grant counties the reports are favorable for an unusually large output of the precious metal and it is safe to predict that the placer mines will figure prominently in bringing about a lively fall trade.

WASHINGTON.

THE TOUGH NUT.—Ruby Miner, April 15: The bonding of the Tough Nut, which was reported as very probable in the last Miner, has now been consummated. The price is \$45,000, to be paid in eight months. The purchasers are California miners, represented in this country by Col. Wallace. The Californians will also make other large investments in Okanogan this season, as soon as Col. Wallace arrives and looks over the ground. The Tough Nut is the pride of Conconully, and is developed by 275 feet of tunneling and a 35-foot shaft. The face of the tunnel shows 10 feet of ore, and at the bottom of the shaft is four feet of high-grade galena and gray copper ore. Work is to be immediately instituted on the mine, and will be continuously prosecuted in the hands of the new management.

Recent Additions to the State Mining Bureau.

Specimens of cassiterite ore from the following tin mines in New South Wales: Brickwood, Uralla district; Pleasoot Creek, Clarence district; and from the Thompson, the Ruby Hill and the Torrington claims at Emuville; also from the same country, quartz crystals with included cassiterite, from Dutchman's Reef, Emmaville; quartz, showing free gold, from Peak Hill; chalcopryite, sulphide, redurbitite (sulphide of copper); native copper, malachite and azurite from the Cobar district; also, pyromorphite

with argentiferous galena; native silver, cerargyrite, native copper and rich chloride of silver from the Broken Hill district, with danaita erythrite from Shaw, near Carcoar; topaz and graphite from Tenterfield, and stibnite from Corangula, near Kempey; coal, with fossil resin, amburite, Bay of Islands coal field, Russell, N. Z.

Cadia nugget, found in 1885 at Cadia, near Orange, N. S. W.

Platypus nugget, Robinson Crusoe, Gully, Bendigo, Victoria, 3376 ounces 6 pennyweights, 1508, found in 1861 five feet below the surface.

Viscount of Canterbury nugget, 1121 ounces to pennyweights, 44420, found at John's Paddock, 1870.

Model of "Thunder" meteorite stromeyerite, J. V. Copeland.

New Incorporations.

The following companies have been incorporated, and papers filed in the office of the Superior Court, Department 10, San Francisco:

GLOBE VINEYARD CO., April 11. Object, cultivating vineyards. Capital stock, \$100,000. Directors—G. M. Lawton, F. Butterfield, E. S. Poble, C. M. Foster, Thos. Sheridan and C. D. Coon.

OAKLAND PRESERVING CO., April 11. Capital stock, \$100,000. Directors—F. Tillman Jr., J. H. Mangels, C. W. Pike and E. A. Denicke.

BIG BEND LAND AND WATER CO., April 11. Capital stock, \$2,000,000. Directors—D. P. Merrill, R. H. Hudson, T. D. Slaven and Beverly S. Taylor.

GORDON ORCHARD AND VINEYARD CO., April 11. Capital stock, \$50,000. Directors—John Cushing, M. M. Johnson, M. V. Cooley, G. M. Stof and E. E. Bush.

ELECTRIC STORAGE AND SUPPLY CO., April 11. Capital stock, \$50,000. Directors—Leon M. Hall, Geo. C. Jensen, Leo S. Robinson, W. B. Josselyn and C. B. Lankeman.

FRIEST VALLEY COAL CO., April 13. Capital stock, \$1,000,000. Directors—A. J. Robinson, F. Sletcher, N. K. Goddard, G. S. Brown and Wm. Strader.

PACIFIC SUIT CLUB, April 13. Object, "to supply the club with suits of clothes." Capital stock, \$10,000. Directors—Geo. L. Maguire, Ferdinand Young, J. M. Searcy, A. Durand, J. H. Maguire and Chas. S. Mix.

ARC AND INCANDESCENT LIGHT CO., April 14. Object, to manufacture, sell and supply electric power and light to the city and county of San Francisco and its inhabitants. Capital stock, \$1,000,000. Directors—J. P. Martin, Frederick M. Pickering, A. J. Bowie, Louis T. Haggin and Irwin C. Stump.

OAKLAND SYNDICATE IMPROVEMENT CO., April 16. Object to reclaim, by filling in, several thousand acres of land north of the railroad mole, west of Sixteenth street, to build warehouses, construct railroad tracks and make Oakland the great shipping point of the coast. Also, the introduction of pure water. Capital stock, \$10,000,000. Directors—George C. Perkins, Eli S. Denison, W. E. Dargie, A. D. Wilder, George T. Hawley, F. Chappell, J. T. Carothers, D. W. C. Gaskill, L. W. Kennedy, Robert McKillian and R. M. Fitzgerald.

MALLARD UNDERTAKING CO., April 17. Capital stock, \$20,000. Directors—W. H. Kelly, A. Olsen, E. Sweeney, S. C. Walsh and M. Savage.

COSMOS IMPROVEMENT CO., April 17. Capital stock, \$100,000. Directors—S. F. Long, L. Vincent, L. G. Schord, T. O. Jephson and F. N. Belgonia.

TILLMANN CANNING CO., (Oakland) April 17. Capital stock \$100,000. Directors—F. Tillmann Jr., Thurlow McMullin, E. A. Engelberg, W. K. Braskett and C. P. L. Leichter.

CALIFORNIA TRANSFER CO., April 18. Capital stock, \$100,000. Directors—C. M. Goodall, W. D. O'Kane, J. Gaffney, A. H. Evans and F. G. Brown.

NATIONAL PUBLISHING CO., April 20. Directors—A. M. Hinman, E. F. Brown, L. M. Babcock, B. O. Hodge and C. E. Griggs.

BUREAU OF EQUIVABLE COMMERCE, April 20. Capital stock, \$1,000,000. Directors—C. K. Teed, G. C. Ludington, R. O. Shear, I. R. Marston, E. C. Hamilton, M. E. Knight and T. P. Marston.

GEORGE OSEAR COAL M. CO., April 20. Capital stock, 1,000,000. Directors—G. R. Tolman, C. B. Adams, A. S. Hulbard, W. L. Higgins and C. F. Brown.

SYNDICATE M. CO., April 20. Capital stock, \$500,000. Directors—A. P. Campbell of Rough and Ready, Nevada Co., J. O. Bushby of Marysville, C. W. Kitts, of Grass Valley, J. C. Turner and F. W. Eaton of San Francisco.

EL DORADO SUGAR REFINING CO., April 22. Capital stock, \$1,000,000. Directors—E. L. G. Steele & Co., E. L. G. Steele, G. A. Moore, Ed. Polhemus, Emmett W. Bee and M. H. McAllister.

PACIFIC REDUCTION WORKS, April 22. Object, to reduce ores. Capital stock, \$1,000,000. Directors—P. A. Campbell, M. C. Jewell, A. Owens, M. C. Walton and John T. Dawes.

KOOPMAN WINE CO., April 22. Capital stock, \$150,000. Directors—G. W. Hendry, G. R. Jones, C. T. Bridges, G. W. Vaughan and G. J. Koopman.

LONA PRIETA PRUNE RANCH CO., April 23. Capital stock, \$12,500. Directors—C. T. Dean, W. H. Quinn, J. A. Thompson, G. J. Buckland, F. Norton and A. E. Kellogg.

MORSE M. CO., April 22. Capital stock, \$1,000,000. Directors—J. A. Canfield, Vernon Wilson, H. P. Blanchard, W. R. Shilling and O. C. Pope.

CAMPBELL INVESTMENT CO., April 21st. Capital stock, \$150,000. Directors—Amy S. Joos, Jesse H. and Donald Y. Campbell, Ellen O. and W. C. B. de Fremery.

PHELPS & ARNOLD CO., April 21. Object, to deal in hardware. Capital stock, \$200,000. Directors—Alanson H. Phelps, Henry A. Arnold, Albert A. Phelps, Jobo M. Arnold and Charles J. Nickerson.

A COMPANY has been organized to more systematically explore the oil-field north of Los Gatos, Santa Clara Co.

COMSTOCK mines produced last week 5035 tons of ore, yielding \$107,932. The total weekly yield is largely increasing.

MECHANICAL PROGRESS

Iron Not Yet Obsolete.

There is no question of greater importance than that of the merits respectively of iron and steel as materials of engineering construction. It is a mistake to suppose, as some persons do, that the dispute has been settled in favor of the latter metal. There have recently happened some noteworthy events to strengthen the belief that iron is by no means dispossessed of its inheritance of use. First, the increased output of ironstone in 1888—as shown in the mining statistics just published—shows that the output of manufactured iron must be an increasing one. Then the decision of Lloyd's Committee with regard to the use of iron in shipbuilding, and the fact of the continued employment of iron for bridge construction, are proofs further of the tendency in question.

At a recent meeting of the South Staffordshire Iron and Steel Institute a very suggestive discussion took place upon the value comparatively of iron and steel in boiler construction. The testimony of those who took part in the discussion was, as is usual in such cases, of a somewhat contradictory nature. While one set of disponents argued in favor of the use of steel for boiler plates, and stated in brief the trustworthiness of this material, other speakers became eloquent about the refusal of certain steel makers to use that metal in the boilers employed at their own works, and pointed to the large prices—as much as £400 in certain instances—paid for single boilers in the construction of which iron was exclusively used.

When metal makers differ it is difficult to decide. But the truth in this, as in many other arguments, lies probably in the middle. As was pointed out at the close of the discussion, both steel and iron will give excellent results when they are separately used. When they are employed in conjunction in the same boiler, and when brass fittings are present, an electrolytic influence is brought to bear, which leads to corrosion of the steel. Again, when tie rods of manganese bronze and phosphor bronze and similar materials are used, electrolytic action is often set up, and the steel plates have been found to be corroded in proportion to those particular points. There seems to be no reasonable doubt that steel is more susceptible of corrosive action than is iron; but, on the other hand, the former metal has many virtues not belonging to the latter. For ourselves, we do not believe there is that rivalry of the two metals that is sometimes spoken of. We expect to see the best Yorkshire and Staffordshire iron in no less request 20 years hence than it is to-day. The qualities of the two metals will gradually be shown up; but we do not expect to see either supersede the other.—*Colliery Guardian*.

The Fusion of Iron.

In the *Metallarbeiter* were recently appeared some observations on the behavior of iron in smelting and casting. It was pointed out that the metallurgical processes by which iron is extracted from the ore, produces at the first running a metal which is chiefly iron, but which also contains carbon, silicon, manganese and other substances. These are impurities; but they have their uses in lowering the melting point of the metal. Pure iron, from its very high melting point, is not well adapted for foundry use. The pig iron, with its high percentage of carbon is much more convenient for castings. When pig iron is re-melted in a cupola, air is brought into contact with the metal and the carbon mixed with it. Part of the carbon is oxidized, and the other impurities such as silicon and manganese together with a small quantity of iron are oxidized and drawn off as slag. Other products of oxidation, carbonic oxide and iron oxide, are dissolved in the molten metal. The aqueous vapor of the air employed in the cupola blast is decomposed into the oxygen and hydrogen; the first of which goes to oxidize the fuel and metal; the latter is dissolved in the metal. Iron possesses the property of absorbing, in the molten state, three times its volume of hydrogen. As the metal cools, the occluded gases (hydrogen and oxide) are set free, leaving traces of their presence in the spongy, porous surface frequently found in solidified masses of metal.

When the molten iron, containing these gases, is run into a mold, the gases are liberated into the casting. This is especially the case when the metal is run at a low temperature. The gases are best eliminated by making the iron very hot, and stirring it well in the ladle before filling the molds. Iron when re-melted has a greatly increased power of absorbing gases and iron oxide. For homogeneous castings it is necessary that all pig iron should be used, without admixture of old castings. Spongy castings are also caused by an improper moulding material which leads to the formation of surface cavities. The bubbles produced by dissolved gases, however, have a bright metallic surface while those due to the molds are covered with a dull film of oxide.—*Boston Jour. of Com.*

ALLOTROPIC FORMS OF METALS.—Writing on some curious properties of metals and alloys, Mr. W. C. Roberts-Austen remarks that the importance of the isomeric and allotropic states has been much neglected in the case of metals. Joule and Lyon Playfair showed, in 1846, that

metals in different allotropic states possess different atomic volumes, and Matthiessen, in 1860, was led to the view that in certain cases where metals are alloyed, they pass into allotropic states, probably the most important generalization which has yet been made in connection with the molecular constitution of alloys. Instances of allotropy in pure metals are: Bolley's lead, which oxidizes readily in air; Schutzenberger's copper; Fritzsche's tin, which falls to powder when exposed to an exceptionally cold winter; Gore's antimony; Graham's palladium and allotropic nickel. Joule has also proved that, when iron is released from its amalgam by distilling away the mercury, the metallic iron takes fire on exposure to air, and is, therefore, clearly different from ordinary iron.

How to Sharpen a Screwdriver.

The screwdriver is found not only in the tool-chest of every mechanic, but in most houses, and in not a few offices. It ranks with the hammer, the saw and axe in general utility, and yet very few persons know anything about how it should be sharpened so as to do its work most efficiently—that is, with the least expenditure of power and the least injury to the head of the screws.

In driving a screw into wood, the force used to press the screwdriver against the head of the screw tends to aid the latter in penetrating the wood; but when we attempt to extract a screw, every pound of pressure that we apply tends to render it more difficult to get the screw out. It therefore becomes very important that the screwdriver should be so formed that it may be kept in the nick of the screw by the exertion of the very least degree of force, for if it has any tendency to slip out, we can keep it in place only by applying pressure, in which case we run great risk of injuring the nick and rendering it impossible to draw the screw.

If we examine a screwdriver in the condition in which it is ordinarily found, we shall find that it presents a section in which the sides of the wedge, in which all screwdrivers terminate, are curves with the convex sides outward. Now, the effect of thus curving the sides of this wedge is to render it greatly more obtuse. Moreover, when we turn the screwdriver, the tendency to slip out of the nick is just in proportion to the obtuseness or bluntness of the wedge, and therefore this form is the very worst that can be chosen. In the hands of most good workmen, therefore, we find that the screwdriver ends in a wedge of which the sides are perfectly straight. This is a very good form, but is not equal to a form in which the sides of the wedge are curves but with the concave sides turned outward. In this way we lessen the obtuseness of the wedge at the extreme point, and produce a turn-screw which may be kept in the nick by the least possible pressure endwise. To grind a screwdriver into this form, it is necessary to use a very small grindstone, and many of the artificial stones found in market answer admirably. Many mechanics would find it to their advantage to keep one of these small grindstones for the purpose, as it could be run in the lathe with very little trouble.—*Technologist*.

STRENGTH OF LEAD PIPE.—Lead pipe will sustain quite a heavy pressure, if it is applied without shock, but in all practical work, in the plumbing of houses especially, the column of descending water suddenly stopped by the closing of a faucet, exerts an increased pressure that will burst pipes which would stand a very much larger weight of still water. Air-chambers should always be employed, where practical, to act as cushions to take up the shock. In a lead pipe, when sudden shocks are created by suddenly cutting off the water, the pipe will generally commence to swell at its weakest point, and thus continue until the power of the pipe is so reduced that at some sudden shutting off the pipe gives way.

SUPERIORITY OF IRON OVER WOOD FOR RAILROAD TIES.—The greater smoothness secured in railway travel by the substitution of metallic for wooden ties is causing their increased introduction in a marked degree. The tie most preferred is a metallic trough, in which the rails rest upon a wooden block, thus avoiding metal contact, and are clamped firmly and securely in place without the use of fish plates or angle bars.

THE TACK INDUSTRY.—Several attempts have been made to establish the tack industry in the South, but they have failed from difficulties in handling the material. The branch of the iron trade is in the hands of New England manufacturers, and is practically confined to Massachusetts. More than two-thirds of the tack business is controlled by that State and fully three-quarters by all of New England.

MATCH-MAKING MACHINERY.—Ingenious machines for the various operations of manufacturing matches have been in use in Scandinavia for some time, and more are expected. Machines for packing the matches have recently been introduced, one of these—the invention of two young Norwegian engineers—having a capacity of 1000 boxes per minute.

A DOUBLE TIRE WHEEL, with springs between the outer tire, is the subject of a recent patent granted in British Columbia.

SCIENTIFIC PROGRESS.

The Mysteries of the Nerves.

It is said that a Philadelphia surgeon has dissected and mounted the complete nervous system of a human being—something never before accomplished. This, however, pertains only to the physical condition of the nerves; but they have a vital action which seems to be in far more immediate connection with the mind or soul than any other portion of the system. We condense as follows some interesting remarks upon this peculiar relation of the nerves:

When we find out the secret of the nerves we shall probably have discovered the secret of life. We shall then, perhaps, know something of the soul, whose very existence is now disputed, and we shall be able to formulate some definite opinion in regard to immortality. Science is slowly moving onward toward that point, and seems at times to have some clew to the mystery. The study of physiology, physical and mental, is little more than the study of the nerves, simply because the nerves are intimately connected with health of body and mind. In cases of prolonged diseases, as long as the nervous system is not completely shattered, there is hope. When the nerves refuse to act, the will, which is the resistant power in the human being, ceases to act also, and death finds an easy prey. There are persons attacked with what seems to be a mortal disorder who obstinately refuse to die. A certain amount of nervous force comes to their relief, which acts on the physical functions and brings back the prostrate individual seemingly from the gates of death.

Sometimes this restoration of sick persons to health seems like a miracle, and there is little doubt that many so-called miracles have been the result of an affluence of nervous force coming from a sudden excess of hope or shock to the system, emanating from no matter what source. Did the alleged saints in the first centuries of the Christian era ever cure the sick? Was a sick man ever restored to health by the touch of a king? Was there ever such a thing as a faith cure? Cures have been performed by each of these means? And yet it is not necessary to suppose that there was any occult power in either saint, king or apostle of faith cure. The whole secret lay in the psychological state of the sick person, in whom confidence in the means, and hope combined with latent nervous force, conspired to set the vital functions again in motion.

The pathological phase is only the border land of the mysterious subject. On the phenomena of the nerves, magnetism, spiritism and hypnotism have erected theories involving a host of strange illusions, but conveying also scientific facts of value. A spirit medium is only a being endowed with exceedingly sensitive nerves. A nervous subject may be hysterical, epileptic, or the victim of hallucinations of various kinds which result in eccentric actions or abnormal physical conditions. The nervous system of some of these persons is in such an excessively morbid state that an external sensation, such as a sudden noise, the ticking of a watch, a pressure on the body, contact with a cold or warm body, a breath, a ray of light, the reflection of some bright object, suspends animation. The subject falls into a sleep, which lasts for a longer or shorter time, and wakes to forget everything that has passed during this period, though it may have continued several weeks. The Witch of Endor was probably a mere bundle of nerves—a spirit medium of Bible times. The Pythoness of Delphi was a hysterical or epileptic capable of extreme nervous exaltation. The witches and sorcerers of the Middle Ages were in many cases the victims of nervous attacks which those about them sincerely believed to be caused by divine or demonic inspiration. In the light of modern science, these characters and events are seen in a less mysterious light.

Several original cases involving hypnotism have, within the last two years, appeared in French courts, and hypnotism is now regarded in France as so dangerous that the Minister of War has forbidden its practice by army physicians. The subjugation of one person to another's will, the dual state in which the subject seems on the confines of another world, is caused by a disorganized nervous system. Even genius, especially poet genius, is stigmatized as an unhealthy psychological state. Everything that is not the duldest and plainest prose of life seems in the process of being transformed into morbid conditions of the body. Does it render a phenomenon less mysterious to prove that it is physical? An object falls to the ground by the law of gravitation. Do we understand that marvelous law better because we constantly see its operation? Chemical atoms attract or repel one another in virtue of a universal law of whose hidden force and meaning we have not the remotest conception. But we are consoled when we discover that something in nature falls within the domain of natural. The phenomenon is classified, but has by no means ceased to be a mystery.

AMMONIA WATER AS A FIRE-EXTINGUISHER.—Considerable alarm was occasioned at Queensferry, near Hawarden, recently, by a serious explosion and fire at the works of Messrs. J. Turner & Co., chemical manufacturers and tar distillers. A still charged with anthracene oil, ten tons in quantity, exploded with terrific

force, owing to the choking of the worm, and shot a volume of flame skyward that illuminated the district over a wide area, and was visible ten miles off. The burning oil scattered itself over the yard and to the pitch house adjoining, where hundreds of tons of pitch were stored. The pitch ignited, and the conflagration assumed alarming proportions. Luckily all the day men had just left the works, but three who had been left were burned. The Sandycroft Fire Brigade was promptly on the spot, and, by using ammonia water from a 50,000-gallon tank, they subdued the fire in an hour and a half.—*Journal of Gas Lighting*.

THE OHIO RIVER OLDER THAN THE MISSISSIPPI.—According to an article in *Popular Science Monthly*, for April, written by Joseph H. James, it appears that the Ohio is an older river than the Mississippi. Mr. James writes as follows: An examination of the geological structure of the country through which the Ohio flows shows none but the extreme end of the valley to be of later age than the Carboniferous era. Portions are, indeed, far older; but the area covered by these, though perhaps extensive enough to allow the development of some system of drainage, was never large enough to develop a stream of any great size. None of the tributaries of the river, either from the north or the south, flow through regions more recent than the Carboniferous, with the exception of the lower parts of the Ohio itself and the Tennessee, which border on the Quaternary. The lowest formation in the valley is the Cincinnati, which is just touched at a single point, and only for a short distance, about 20 miles above the city. It may be stated then, that since the close of Carboniferous time the river has flowed mainly in the same channel. The vast antiquity of the river is thus easily established, and the existence of the wide valley, with its broad bottom lands, is readily accounted for. The story of the river during the long period of preglacial time would be simple. For ages its waters were probably poured directly into the Gulf of Mexico, an arm of which extended northward into the continent at least as far as the present site of Cairo, Illinois. In later times the Mississippi-Missouri began the formation of a delta, which, gradually extending, has left the Ohio a tributary merely of the mighty "Father of Waters."

A LOCK FOUR THOUSAND YEARS OLD.—An Egyptian lock has been found which was in use more than 4000 years ago. The old Egyptian lock was not made of metal, like those we use now—days, but of wood, and the key that opened it was wooden, too. On one side of the door to which it was fastened there was a staple and into this staple fitted a wooden bolt that was fixed to the door itself. When this bolt was pushed into the staple as far as it would go, three pins in the upper part of the staple dropped into holes in the bolt, and held it in its place, so that it could not be moved back again until the pins were lifted. The key was a straight piece of wood, at the end of which were three pegs the same distance apart as the pin which held the bolt firm. When the key was pushed into the bolt through a hole made to receive it, the pegs came into such a position that they were able to lift the pins that fixed the bolt, and when these were lifted the bolt could be lifted out of the staple.—*Trade Mail*.

HOW THE MUSKRAT BREATHES UNDER ICE.—Animals that breathe by means of lungs can prolong their stay under water only through special anatomical arrangements, or by having recourse to some extraneous means. Mr. W. Spoon of the Elisha Mitchell Society, who has hunted the muskrat in winter, asserts that the animal, when obliged to traverse, under ice, a pond so wide that it cannot keep up its breathing, stops from time to time and exhales their from its lungs. This air, being confined by the ice, becomes oxygenated in contact with the water, and the animal, taking a fresh inspiration, dives in order to begin its swimming again a little further along. It appears that other observers have found that if this air is dispersed through the ice being struck, the animal is killed through asphyxia.

MAGNETIC ROCKS.—At the Royal Academy of Lyncei on Dec. 18th, says the *Electrician*, Signors Sella and Oddone gave an account of some researches on the distribution of magnetism in certain regions on the Alps. They have found a number of magnetic foci, and record that the rocks which present distinct magnetic properties are magnetite, serpentine, diorite, melaphyre, and syenite. A magnetic rock was observed by Signor Sella on Punta Ginfetti, in the Monte Rosa group, and as it presented traces of fusion on its surface, as if it had been struck by lightning, it is suggested that this circumstance has endowed the rock with its magnetic properties.

THE UTILITY OF THE MICROPHONE for observation of earth tremors and noises is becoming generally recognized. Italy has for some time held a foremost place among the nations which have taken advantage of the special adaptability of this instrument. It is also now found that photography possesses admirable capabilities in the way of supplementing the work of the microphone in making these delicate records.

LENGTH OF DAYS.—The longest day of the year at New York is 15 hours, at London 16½, at Hamburg 17, at Stockholm 18½, at St. Petersburg 19, at Tornea, Finland, 22, at Spitzbergen 23 and one-half months.

GOOD HEALTH.

The Sugary Watermelon.

The following, from an old exchange, will be read with interest in view of the approaching season for indulgence in melons and fruit:—It is delightful to have science spare here and there a tree of love and old fancy. There has been such a sweeping and mowing down of human comforts that we once at least esteemed as such, in regard to eating and sleeping and the general manner of living, that it has seemed at times that the sanitarians and the scientists were determined to convert us into the veriest machines, and leave us nothing of the sweet and old-time indulgences that in the innocence of youth and the maturity of age we thought to be harmless.

For instance, we have been told that the watermelon is "aquish" that it contains but a very small percentage of nutritive elements—as if man must indulge in nothing except with an eye single to the brawn of his composition; that the melon is a seed and home of malaria, that convenient esopogon for every ill not otherwise defined; that, in short, the less of the rich, ripe and toothsome melon we eat the better for us. Such has been the gospel of science, or at least of preaching by a grand army of advisers, that the small boy has heroically defied and grown up to stout manhood "just the same."

Now, after many years, the scientists settle down to the doctrine that the watermelon is not dangerous to health, provided always we wrestle with this filling and luscious fruit of the field when it is fully ripe. That, indeed, its action upon the secretive organs is rather beneficial than otherwise, unless our indulgence degenerates into the glint of intemperance; that more of melon and less of meat in the summer season, is decidedly beneficial. As for the age they now tell us that there is no more of that shaking ill in the dripping sugary melon than in any other fruit, and there is none in any if it is taken at the right time and in due moderation. Unfortunately we do not know who to thank for this generous advice, and this overthrow of a bngahoo that has occasioned many a boy exquisite tortures because of enforced abstinence. But as an integral part of the grand army of melon lovers science has our thanks."

HAS EVERY DISEASE ITS REMEDY?—The theory that for every disease there is a remedy, if we could only find it, is as pleasing as it is plausible. It labors under the doubt-inspiring fact, however, that it is of a *priori* origin. So many speculative hypotheses of this kind have been scattered to the winds by the labors of the inductonists that one is sometimes tempted to take up the unphilosophical position that whatever rests solely upon an *a priori* basis must necessarily be false. That would of course be absurd. But is it the case, as matter of fact, that for every disease there is a remedy, if it could only be found. Before answering this question we must turn the ambiguous word "remedy" into something more precise. If by "remedy" is meant "cure," then an exceedingly strong position may be taken against the hypothesis and the position is this—that up to the present time experience has not furnished us with a single remedy which can properly be called a "specific cure" for a "specific disease." Now, this is clearly a fundamental and also a staggering fact for those who believe in the doctrine that a remedy for every disease under the sun will be found if only we look carefully enough for it. If the world is not very old, neither is it very young; and if past experience has not furnished us with one single substance which definitely and certainly cures any one certain disease, there is a strong presumption that such substances will be as difficult to find in the future as they have been in the past.—*London Hospital*.

REST AS A MEDICINE.—A physician, writing of rest as a medicine, recommends a short nap in the middle of the day for those who can take it, as a beneficial addition to the night's sleep. It divides the working time, gives the nervous system a fresh hold on life, and enables one to do more than make up for the time so occupied. A caution is given against the indulgence in too long a sleep at such a time, under a penalty of disagreeable relaxation. There has been much discussion regarding the after-dinner nap, many believing it to be injurious, but it is, nevertheless, natural and wholesome.

A CAUSE OF PNEUMONIA.—Dr. F. W. Curtin reports two cases of pneumonia which seem to have a traumatic origin. A boy of eleven was forcibly struck on the left side of the chest with a hatchet. Cough and dyspnea came on in four hours, and the physical signs of pleuropneumonia at the base of both lungs later. The second case was a man of 22 who strained his right side by trying to prevent the fall of a sack of malt. He developed all the signs of pneumonia and died, both lungs being in a state of red hepatization.—*Brit. Med. Jour.*

WILL ALOES CURE HYDROPHOBIA?—It is reported that the American aloes is a very effective remedy. Dr. Patron relates a case of a boy in Peru, who having been badly bitten by a dog, notwithstanding cauterization of the wound, in a few days showed unmistakable signs of having hydrophobia. One day when not

watched he ran into the fields and gathered some leaves of the aloes, which he chewed and swallowed; the symptoms of the disease began to abate and the boy recovered.

USEFUL INFORMATION.

Air-Blasting for Rain.

We have all heard of aerial concussion as a mooted cause of rainfall. Systematic trial of this method is now to be made, by order of Congress, under the auspices of the Department of Agriculture. We read in the *Scientific American* that Senator Farwell of Illinois proposes to devote himself to the scientific work of trying to produce rain by the firing of cartridges of gun-powder or nitro-glycerine high up in the air. During the last session, Congress appropriated \$2000 for carrying on experiments of the kind, but Senator Farwell does not intend to limit himself to this small sum, and will, if necessary, contribute from his own pocket such sum as may be necessary to complete the trial to his satisfaction. The main fact on which the theory of the experiments is based is the circumstance that heavy cannonading is often followed, after a day or two, by rain. Acting on this observation, attempts have been made at intervals, during the last hundred years, to produce rain by firing cannon and producing concussions of the air in other ways, but without much success. Senator Farwell, however, says that during the construction of the Central Pacific railroad through the arid region east of the Rocky mountains, where a great deal of blasting was necessary, it rained every day that there was blasting. For this reason, he thinks that a sharp explosion of nitro-glycerine, produced high up in the air, would be more effective than cannon firing near the ground, and he proposes to send up balloons in the dry portions of Western Kansas and Colorado, furnished with torpedoes and slow matches, by which he hopes to obtain a concussion extending for 50 miles in every direction.

KEM KOM is the outlandish name given to a new chemical compound owned and introduced by the Standard Coal and Fuel Co., Boston, for treating coal and other combustible substances. The effect upon coal treated by this compound is said to increase the heat and the steam, economize time and fuel, consume the smoke and poisonous gases which ordinarily arise from burning coal, destroy the clinkers and soot, and materially reduce the quantity of ashes. It is claimed that by treating coal with kem-kom, from 15 to 30 per cent of the coal is saved, that is, coal thus treated will produce the same result and give more heat and steam than from 20 to 30 per cent more coal not treated. It is further claimed that by using this compound on bituminous coal, from 80 to 90 per cent of the smoke is consumed; all the gases that are so obnoxious and unpleasant are destroyed; thus a saving of coal and time, as well as many other advantages, can always be relied on, which together renders this a most important discovery, and one which looks as though it would revolutionize the big coal bills which are such important factors in the running of factories, electric light and power stations, and similar places; and so it will if it accomplishes half of what is claimed for it—a matter which looks extremely doubtful to one standing at this distance from it.

A SNEAK THIEF is usually regarded as a creature of low and depraved tastes. But there is or was one a few weeks since in Providence, R. I., who seems to have an ambition to reach a high elevation in some way. He climbed by night to the top of the Electric Light Co.'s chimney, 250 feet high, presumably by the lightning rod, and stole the platinum tips from the top of the rod. The theft has entailed considerable expense upon the company as the rod will have to be retipped, and can only be done by building a platform about the top of the chimney. Human audacity could scarcely attain to a greater height, especially by such slender means. The company ought to forgive the theft and appoint him trimmer to their lofty light towers.

USES OF THE RARE METALS.—Some rare metals, possessing special qualities are required for certain work. Thus palladium is used in making some parts of time-pieces, and iridium for the points of gold pens, and the unalloyed has no idea of the value of such products. Vanadium coets, for instance, 123,900f. per kilogramme; zirconium, 79,295f.; and lithium, which is the lightest of metals, 77,090f. per kilogramme. Rhodium, which is extremely hard and brittle, and is only fusible at a very high temperature, fetches 25,330f.; and iridium, the heaviest substance hitherto discovered, coets 12,005f. per kilogramme. It will, therefore, be seen that gold and silver are far from being the most precious metals, as far as their market value is concerned.

ANOTHER ALLEGED WHITE LEAD IMPROVEMENT.—G. G. Coleman, of Chicago, claims to have discovered "a method of manufacturing white lead in such a cheap, quick way that the trust which now controls the production of this staple must go to smash." He has already exhibited to a number of Chicago paint dealers some white lead said to have been made by his process. They declared the article to be of good grade. The process has not been ex-

plained further than it requires only 12 hours as against 60 days by the old method, and that no acids are necessary. The basic material used is pig lead.

PAPER HORSESHOES.—There seems to be a great interest in seeking for the best material out of which to make horseshoes. The latest application is paper, which, it is said, will never become smooth or slippery. The shoe, it is said, is simply glued to the foot by some substance which is not affected by water. The shoe is cut out of a plate of papier mache, made as solid as metal by great hydraulic pressure.

THE WOOD WORKER.

DARKENING OAK.—To render new oak wainscoting and oak furniture dark and give it an antique appearance, we have it from good authority that ammonia is the cleanest, best and cheapest material that can be used. The liquid stains commonly used are apt to raise the grain of the wood, make it rough, and it is with difficulty evenly applied, whereas in the use of ammonia it is simply the fumes that color the wood, and do it so completely that it is difficult to tell whether the wood is really new or old. A correspondent in the *English Mechanic* gives the following process of treatment, which he considers the best, after trying the various other processes used by builders and cabinet-makers to darken woods: "Oak is fumigated by liquid ammonia. The wood should be placed in a dark and airtight room (in a big packing-case, if you like), and half a pint or so of ammonia poured into a soap-plate and placed upon the ground in the center of the compartment. This done, shut the entrance and secure any cracks, if any, by pasted slips of paper. Remember that the ammonia does not touch the oak, but the gas that comes from it acts in a wondrous manner upon the tannic acid in that wood, and browns it so deeply that a shaving or two may actually be taken off without removing the color. The depth of shade will entirely depend upon the quantity of ammonia used and the time the wood is exposed. Try an odd bit first experimentally, and then use your own judgment."

TURNING A BALL.—A mechanic who has tried to duplicate a croquet ball by hand in an ordinary wood-turning lathe has found that the job of turning a sphere was greater than he expected. It can be done by placing a square piece of wood against the face plate of the lathe and holding it by pressure from the tail stock. Turn carefully as near as possible by the eye, then with a leadpencil make a mark around the center of the ball, remove the block from the lathe and turn it about one-fourth way around, replace in the lathe and take off light chips until every part of the pencil mark is removed. This will bring the ball nearly perfect; perhaps making one more change of center will finish the job. The philosophy of this method is that the mark made with the pencil around center of the ball is a perfect circle and upon changing axis of ball and working to this circle the perfect circle becomes a perfect sphere. A little practice will enable a good turner to run off nearly perfect balls with considerable speed.

A NEW AND VALUABLE SHINGLE MACHINE.—The Porter, Gage Co., of Ballard, Washington, if reports are true, have a most valuable machine for cutting shingles. The cedar bolts are steamed five hours, then run through a trimmer, then they go to the cutting knife, which is a heavy knife running at 170 strokes a minute. The shingles are cut off at that rate apparently as easy as a cheese would be cut. The shingles come from it almost too fast to count. They are hot and steaming and cut smooth. They are afterward treated the same as other shingles. It is claimed that the steaming drives out all sap and prevents them from ever warping. The highest cut ever made in a ten hours' run was 96,000. This machine makes no sawdust, hence no waste. The shingles are much smoother than sawed ones, in fact they have the appearance of being planed. There are but four of these machines in operation.

TERRA COTTA LUMBER.—Near Melbourne, Australia, is a factory of terra cotta lumber from clay and hardwood sawdust. In the process of manufacture the sawdust is spread and left lying on the clay in the pit from 36 to 40 days to allow it to sweat. Both are then mixed thoroughly, stones being eliminated, the mass is molded to the desired shapes, steam dried, and the sawdust roasted out in a kiln. The product is guaranteed to be proof against fire, heat, cold and vermin.

OAK FURNITURE.—Furniture manufacturers believe oak will continue to be the popular wood for furniture for some time. Mahogany is, of course, the wood for expensive furniture, but for goods of medium price oak will still be the proper thing. Walnut would have its day again if a supply could be had. Stained woods have had their day.

WELL-SEASONED WOOD.—To test wood whether it is well seasoned, put a small quantity of tincture of iodo on a part freshly sawn or cut. If it assumes a dark, nearly inky, color, then the wood is good and at least one year out; but if the place assumes a yellow color, then the wood is quite new and not fit to use.

ELECTRICITY.

FACTS ABOUT ELECTRICITY.—"All the energy in the world," said Dr. C. F. Coandler, in a recent lecture before the Columbia School of Mines, "come from annuins. Even the energy in the electric battery that rings the doorbells of our homes has its origin in the light of the great solar system. The force in the copper wire that sets the bell to ringing comes from the zinc plate in the battery jar. The energy in the zinc plate comes from the Anthracite coal with which it was burned when taken from the mines, and, finally, the energy in the Anthracite coal was put there by the sunlight that fed and nourished it when it existed, ages ago, as trees and plants. An interesting misapprehension that exists in the minds of a good many persons, is concerning the vital dangers that lurk in the presence of, say, a thousand volts. The newspapers often tell us that a man has been killed by such a pressure, whereas, in fact, such a pressure alone could not kill a humming bird. I have frequently caught in my hand sparks possessing an electro-motive force of 100,000 volts without feeling anything more than a very slight burn. The danger arises only when the volts are reinforced by a good many amperes or currents, as when one takes hold of a charged wire. Then one feels a shock that is unmistakable, because the force of a great many currents in the wire suddenly decomposes all the fluids in his body. The salt in the blood at once turns to chlorine gas, and the man whose veins are charged with this deadly poison cannot in reason be expected to live long."

ELECTRICAL DEVICE FOR LOCOMOTIVES.—An interesting invention is now undergoing thorough investigation, which promises much for the improvement of railway traffic, both in increasing the safety of railroad and the pulling capacity of a locomotive. The invention consists of a small dynamo and an auxiliary engine placed upon the locomotive in such a way as to be easily operated, furnishing a current of small force but large quantity, which is made to pass from one pole of the dynamo to one pair of driving-wheels, thence along the rail to the other pair of driving-wheels, thence to the other pole of the dynamo, thus forming a traveling circuit, moving at all times with the locomotive. By means of this current, an inductive weld is caused between the wheels and rails at the point of contact, preventing the slipping of wheels. The working model of the device shows an increase of 400 per cent in the hauling power of the locomotive. The model without the application of the current would not mount a grade of 15 per cent, but when the current was applied, it mounted a grade of 35 per cent. A locomotive is now being equipped with the invention to test it on the Baltimore & Ohio railway.—*Modern Light and Heat*.

ELECTRICAL TRANSMISSION OF POWER.—In the recent competition instigated by the Cataract Construction Co. for the utilization of the power of Niagara Falls, there were fifteen different schemes presented, of which seven proposed electrical transmission of power, two hydraulic, and six pneumatic. Of the electrical schemes two advocated alternate current transmission at 5,000 and 10,000 volts, and the remaining five continuous-current transmission at potentials varying from 1,600 to 4,500 volts. The fact that the number of electrical schemes proposed was less than the sum of the pneumatic and hydraulic plans, said Mr. Gisbert Kapp, in a recent lecture before the Society of Arts, London, showed that electrical engineers were scarcely prepared to deal with a problem of this magnitude. At present the limits of distance for the electric transmission of power at a reasonable cost are about four to five miles. Beyond the latter distance the economical voltage for 500 horse power is beyond the capacity of one machine. Practically, the extreme limit for direct currents is between 2,000 and 3,000 volts.

THE PROPER DIVISION OF POWER IN SHOPS is attracting more and more attention among mechanical engineers. It is well known that the only time when power is being transmitted economically is when all the machinery is running, for then each has its own share to contribute to the cost of driving the shafting. In many places, there are so many countershafts and idle belts at work that when a small portion of the machinery is being driven, it makes but little difference in the power-bill, and yet we find them running noon hours and night-time to accommodate an outside job, where only a small drill lathe, or something of the kind, is occasionally required. Division of power is as important as division of machinery, and it looks as though electrical driving would solve this problem completely, for we find a small dynamo is kept in many places all ready to be set up behind any machine when a lathe or a planer is to be driven in the night-time.

AN ELECTRIC CLUB.—One of the latest proposed applications of electricity is a policeman's club that contains a galvanic battery. When the rowdy seizes the club, thinking to wrest it from the policeman, the rowdy receives an electric shock, which astonishes and paralyzes him, rendering his capture easy.

To make paper stick to a wall that has been whitewashed, wash the wall with vinegar water,

SAN FRANCISCO:

Saturday, April 25, 1891.

TABLE OF CONTENTS.

ILLUSTRATIONS.—High-Class Cornish Rolls for Ore; Improved Rock-Breaker, 257. Our Distinguished Visitor, Benjamin Harrison, President of the United States, 265.

EDITORIALS.—Government Ships to be Built Here; Quartz-Crushing Appliances, 257. Passing Events; Terrorite; Nevada Salt; California at the World's Fair; The President's Visit, 264. President Harrison, 265.

CORRESPONDENCE.—Loss of Gold; Nevada County's Mines, 253. Placers of Sonora, Mexico; Forestry at the World's Fair; The Stanford University, 259.

MECHANICAL PROGRESS.—Iron Not Yet Obsolete; The Fusion of Iron; How to Sharpen a Screw Driver; Strength of Lead Pipe; Superiority of Iron Over Wood for Railroad Ties; The Tack Industry; Match Making Machinery; A Double Tire Wheel, 262.

SCIENTIFIC PROGRESS.—The Mysteries of the Nerves; Ammonia Water as a Fire Extinguisher; The Ohio River Older than the Mississippi; A Lock Four Thousand Years Old; How the Muskrat Breathes under Ice; Magnetic Rocks; The Utility of the Microphone; Length of Days, 262.

GOOD HEALTH.—The Sugary Watermelon; Has Every Disease its Remedy? Rest as a Medicine; A Cause of Pneumonia; Will Aloes Cure Hydrophobia? 263.

USEFUL INFORMATION.—Air-Blasting for Rain; Kem Kom; A Sneak Thief; Uses of the Rare Metal; Another Alleged White Lead Improvement; Paper Horse-hoes, 263.

THE WOOD WORKER.—Darkening Oak; Turning a Ball; A New and Valuable Shingle Machine; Terra Cotta Lumber; Oak Furniture; Well-Seasoned Wood, 263.

ELECTRICITY.—Facts About Electricity; Electrical Device for Locomotives; Electrical Transmission of Power; The Proper Division of Power in Shops; An Electric Club, 263.

MINING SUMMARY.—From the Various Counties of California, Nevada, Arizona, Colorado, Idaho, Montana, New Mexico, Oregon, Utah, Wyoming, 260-261.

MINING STOCK MARKET.—also in the San Francisco Stock Board, Notices of Meetings, Assessments, Dividends, etc., 263.

MARKET REPORTS.—Eastern and Local Metal Markets; Coal and Coke, etc., 263.

Passing Events.

The city is preparing for an elaborate reception of the Chief Magistrates of the Nation who arrives here on Saturday evening from the South. The city will be illuminated that night, and will be in gala attire for a week to come.

The armored cruiser Monterey, which is to be launched on Tuesday, is the third of the Government vessels built in this city, and there are two more in process of construction. In the future, San Francisco is sure to get her share of work in building the new navy of the United States, having proved her ability in this line.

Quartz mining is alive all over the State, and a prosperous year in this industry is predicted. The blue gravel regions of the northern end of the State are also receiving the attention due them, and very favorable prospects are apparent.

The reports from the Pahump valley, Nevada mines, about which there was some excitement a few weeks since, are not such as to warrant many people going in that direction, as the heat claims are all located.

There is some little excitement in Salt Lake over the prospects of the Deep Creek country, where some very promising mining properties are being opened.

The Seattle Knights of Labor assert that efforts are being made to bring 600 miners from Illinois to take the places of the strikers in the Newcastle and Gilman mines. There are already a number of coal miners idle in Washington.

The Pollok Gold-Extracting Process.

The Grass Valley Gold-Extracting Company is an English corporation with J. W. Higginbottom resident manager, and W. L. Holmes metallurgist in charge. The company's works are located one and one-half miles N. E. of Grass Valley, on the line of the Nevada C. N. G. R. R. The system employed is known as "The Pollok Gold-Extracting Process."

The ore is crushed, passed through a rotary drier, then through rolls, and screened. The coarse particles are returned to the rolls to be recrushed, and when crushed, the ore is discharged into a large storage hopper. From this hopper, charges of from six to eight tons are taken and charged into Bruckner furnaces, and here given an oxidizing roast, or when required, a chloridizing roast, of from six to 12 hours. The roasted ore is then discharged on to an iron cooling floor, and thence to scales.

When weighed, the ore is dumped into revolving chlorinating cylinders, 4500 pounds to a charge. Here bisulphide of soda is added, and water fed into the cylinder through a trunnion, until the cylinder is filled to a stopcock. All air being excluded, pressure is then turned on to the water, through the trunnion pipe, up to 100 pounds to the square inch. The bisulphide of soda is dissolved in the water, and the free sulphuric acid thus liberated, combining with the calcium of the leaching powder, thus sets free the chlorine in the leaching powder. The chlorine gas thus set free is liquefied by the 100 pounds to the inch pressure, in the cylinder, and is forced through, and with the rotary motion, brought in direct contact with every particle of ore in the cylinder. At the expiration of one and one-half to two hours time, the cylinder is stopped rotating, the blow-off valve opened, and the escaping gas and liquor conducted on to the filter beds. These are rectangular, three feet in depth, four in width and ten in length, lined with chemically pure lead and painted with P. P. paint. After the gas has escaped, the manhole of the chlorinating cylinder is opened and the vessel given a half-turn, thus discharging all of the contents of the cylinder on to the filter bed. The filter bed is then connected with a powerful exhaust and force-pump, and the chlorided solution drawn through the ore and filtering medium, and thence pumped into lead-lined and painted settling tanks. Each tank has a settling capacity equal to the chloride liquor from three charges.

The liquor is now allowed 12 hours to settle. Any oxalons matter, such as lead or magnesia, is precipitated by the addition of sulphuric acid. The clear liquor is then drawn off into precipitating tanks. Here the gold held in solution is precipitated by the addition of sulphide of iron. The precipitate is then given 24 hours to settle. Then the liquor is siphoned off into a third tank, where it remains for another 24 hours.

In this tank the gold carried over in suspension from the precipitating tank is allowed to settle, and the final solution passed through a special filter, which recovers all of the gold. This filter is cleaned up semi-annually, while the gold from the precipitating tank is taken up every 15 days. The gold is washed in a dilute solution of sulphuric acid to remove the salts of iron. The resulting product is then dried and fused into bars, the gold obtained being 990 fine.

The works have a capacity of 50 tons a day; the company purchases ore on their assay value or work on a percentage. The Pollok patent is in successful operation in Chili, Australia and Africa.

The Grass Valley plant is the only one in operation in North America. The works of the company are very favorably situated both for receiving and handling the ores to be treated. On the hill above the works, is the mansion of the manager; at the side of the railroad tracks, the company's offices, and immediately opposite the works, which extend down the mountain's side to its base, thus making the works as near automatic as possible, and giving the desired pressure from the water pipe.

The motive power of the works is water. The metallurgist in charge, Mr. W. L. Holmes, is justly proud of the assay office connected with the works. It is doubtful if a more complete assay office is to be found in the State. These works are not only a great factor in the

profitable working of the sulphurets and high-grade ores of Nevada county, but will prove equally valuable to the owners of high-grade and especially rebellious ores from all points, thus not only proving a valuable acquisition to the methods employed in the treatment of the ores of the State, but very materially lessening the cost, as well as increasing the returns.

Nevada Salt.

None of the salt companies of Nevada are at the present time very large producers, with the exception, perhaps, of the Desert Crystal Co. at White Plains. The companies in that State now producing any salt at all make only enough for local use, the ore mills in the region consuming most of it.

The salt supply of Nevada has an interesting history. For several years at first the salt used in the mills running on the Comstock ores was all imported from California, at a cost of \$140 per ton and sometimes more; then the supply was obtained from Rhode's marsh, lying nearly 200 miles to the southeast, whence it was packed in on camels brought into the country for the purpose, much of the road between the marsh and the mines being sandy. Through recourse to this expedient the cost of the article to the millmen was reduced nearly one-half. When, a few years later, the Sand Spring deposit, nearer the mines by 80 miles, was discovered, the price underwent a further reduction. In 1867, the Central Pacific railroad having reached White Plains, the deposit there was utilized, further reducing the price of salt to the Comstock consumers and excluding the Sand Springs product from that market. The extension of the Central Pacific and the building of other railroads in that State has served in other cases to shift active salt production from one locality to another.

Most of the salt consumed in that region being employed for ore reduction, is used as gathered on the marshes, it serving for that purpose better than if refined, owing to the considerable percentage of soda it contains in its natural state.

California at the World's Fair.

There is an unfortunate outcropping of affairs with reference to the representation of our State at the Columbian Exposition. The State Commissioners, find on assembling for conference that their work may be sharply arrested by the attitude which the National Commissioners may take in shaping the rules for the fair. It has been reported by telegraph that some of the National Commissioners, including at least one of California's representatives in that body, will take ground against separate State displays, and order all the articles placed under the headings contemplated by their scheme of classification. This would be a serious disappointment to the people of California who have been moved to generous appropriation for this work wholly upon the idea of having a separate California display, and not only that, but not to do this would render the appropriation of \$300,000 unavailable, for it was not made as a contribution to the World's Columbian Exposition's general fund. If it is not expended as intended by the Legislature, for a special exhibit, it cannot be expended at all, because the Constitution requires that expenditure of State money should be made under State auspices and not otherwise.

The chances are, then, if the National Commissioners insist upon a segregation of California material, that the State Commissioners would resign as having nothing to do, and the \$300,000 would remain in the State Treasury, which may be the best place for it after all. This will certainly be the popular decision on the matter if the National Commissioners do not show more regard for the wishes of the California people than they have hitherto.

THE strike in the Delhi mine, near Columbia Hill, Nevada county, is an important one. The mine has been opened about five years, and has paid \$330,000 in dividends. A great deal of money has been spent in development, one of the tunnels costing \$40,000 for its 1400 feet. The ledge is four feet wide, and it is believed will mill from \$80 to \$90 per ton. It is not specimen rock, but is of high grade.

THE State Mining Bureau Museum has been robbed of a number of rare articles, though none of them were of great intrinsic value.

The President's Visit.

The President has been visiting Los Angeles, Riverside and San Diego. His westward journey has been an ovation throughout. The Presidential party entered the State of California at Fort Yuma at 4:50 o'clock Wednesday and was presented with a large quantity of beautiful flowers and fruits. The entire party was asleep at the time, so did not see the presentation committee. When the Presidential party reached Iodio at 8:15 o'clock, it was received by a large and influential delegation, headed by Governor Markham, who made the following address of welcome:

Mr. President: As the Governor of California, and in her name and on behalf of her people, I greet you on the very threshold of her territory, and bid you a most hearty welcome to our State. This I do on behalf of all her people irrespective of party affiliations, and, sir, as a proof of this, I shall soon take pleasure in introducing to you distinguished representatives of both political parties, who are with me and who heartily join in welcoming you as the Executive of our great nation.

Let me assure you that we fully appreciate the great effort you have been obliged to make in order to visit our coast; but I am confident that you and your party will feel repaid when you see the wonderful features so peculiar to our State, and of which every Californian is so justly proud, and of which so little is known or correctly understood by the people of the great East.

California, Mr. President, is an Empire of itself, 700 miles in length and 300 miles in width, thus affording every gradation of climate and almost every production of any country under the sun.

And, sir, permit me to say that, though we are hundreds of miles from the National Capital, and separated from the people of the East and South by what may seem endless plains and impassable mountains, yet we are in close sympathy with them in all national affairs and are exceedingly proud of the position we occupy in the great sisterhood of States over which you have been called to preside.

You will be convinced of these facts, Mr. President, by the cordiality with which you, as the representative of the whole country, will be received in every portion of the State.

I think it but just to the immediate portion of the State upon which you are entering, to say that almost the whole of the wonderful development which you will witness is the work of the last decade. Ten years ago, with few exceptions, what is termed Southern California was a desert, barren and uninviting, but now a veritable garden, beautiful to behold, and producing millions of dollars annually, hiding fair in time to control the markets of the world with her products. Ten years ago Los Angeles was but a back-country village, with less than 12,000 inhabitants, but now a city with nearly 60,000, with all the modern improvements for the comfort and convenience of man. What is true of her progress is also true of San Diego, San Bernardino and many other places.

Pursuing your journey to the north, you will see the beauties of Santa Barbara, the immensity of the San Joaquin valley—the natural granary of the world, developing like magic into orchards and vineyards, and so on to the magnificent city of San Francisco.

And, Mr. President, when you reach that great city I want you to remember that all the evidences of prosperity you will see, and they are countless, are but evidences of the immense resources of this State; for that city has been created, built and sustained out of the money flowing in from the sale of our own products, which can be said of few cities of importance in the United States.

It has been arranged for you to see the central portion of the State fairly well, and I need not dwell on what is in store for you, as I do not believe such a country exists outside of California.

I regret that your visit is so arranged that you will not see in detail the northern counties, which, I assure you, are of themselves worth a trip across the continent. It is impossible to describe them and I will not attempt it.

In some of these counties lie millions and millions of dollars in gold, awaiting the discovery of a process of development, which will not injure other important interests and for which we must depend upon the General Government. I am confident that did these mines lie in either France, England, Germany or Russia those governments would take immediate steps to work them.

I regret exceedingly that the short time you will stay among us will not permit you to see the natural scenery for which our State is so noted, among which I need only mention the wonderful Yosemite Valley, the great redwood forests of the north and the mighty mountains with their wealth of beauty.

Mr. President, before closing, I want to ask you to take particular notice of our great lack of national public improvements, of our extensive shipping interest, our almost endless coast lines, almost defenseless and absolutely without harbors of refuge except at San Diego and San Francisco, either of which could accommodate the commerce of the world, but located nearly 500 miles apart.

The President in reply said he would not undertake, while almost choked with the dust

of the plains he had just left, to say all that he hoped to say in the way of pleasant greetings to the citizens of California. Some time when he had been refreshed by their olive-oil and their vineyards he would endeavor to express his gratification at being able to visit California. He had long desired to visit California and it was the objective point of this trip. He had seen the Northern Coast and Puget Sound, but had never before been able to see California. He remembered from boyhood the excitement

President Harrison.

President Benjamin Harrison, of whom a good portrait appears upon this page, was born at North Bend, Hamilton county, Ohio, August 20, 1833. His father was John Scott Harrison, who served his district two terms in Congress. His grandfather was that famous leader and general, who, after a life of brilliant and distinguished service in the form and the field, was elected President of the United

States. He commenced the study of law at Cincinnati, Ohio. In 1853 he was married, and in 1854 he established himself at Indianapolis, his present home. On the breaking out of the Rebellion, he left home, a successful practitioner, and all that makes life pleasant, in response to his country's call for her defense. The same diligent application that contributed to his success in peace enabled him to succeed in war, and the proclamation of peace found him wearing the stars of a general. In 1881 he was elected to the

worked now, however, than ever before, and the number is sure to increase as our cities grow. In the line of marble, there are only a few quarries but they are being properly opened and developed and are gradually increasing their output.

The quarry in Inyo county is making shipments steadily and developments are such as to justify belief that railroad communication with it will soon be made, as it seems certain that the present railroad facil-

OUR DISTINGUISHED VISITOR, BENJAMIN HARRISON, PRESIDENT OF THE UNITED STATES.

of the discovery of gold and had always distantly followed California's growth and progress. The acquisition of California was second only to that of Louisiana and the control of the Mississippi river. It secured us this great coast and made impossible the ownership of a foreign power on any of our coast line. It has helped to perfect our magnificent isolation, which is our great protection against foreign aggression. He thanked the Governor and committee for their kindly reception and assured them that if he should have any complaint to make of his treatment in California, it would be because its people had been too hospitable.

States, after the most exciting campaign of 1840. His great grandfather was one of the heroes of the Revolution, Governor of Virginia, and a signer of the Declaration of Independence. One of his ancestors was a general of the Commonwealth of England, before Cromwell's usurpation, and whose unflinching Republicanism cost him his life in the early days of the Restoration. His immediate descendants came to America and founded the family in this country.

Benjamin Harrison received a classical education, and is a graduate of Miami University, Oxford. Immediately after graduation, he

United States Senate, serving out his full term. In 1884 he was prominently canvassed as a Presidential candidate, and in 1888 was nominated and elected President, taking the oath of office March 4, 1889.

California Marble.

The marble industry of this State is one which now shows great promise. The resources in the matter of building stone in California are not equal to those of other localities, though there are many places where quarries might be opened. There are many more being

ities cannot much longer handle the shipments of this one industry.

In Amador county the stockholders of the Carrara marble quarry are now about to decide upon the most feasible route for a road from the quarry, which is on Sutter creek at a point north of Pine grove, to connect with the main road. There are two practicable roads. The *Amador Ledger* says:

The marble of this quarry is looked upon by the experts of the city as by far the best found on the coast. The stock has been snapped up readily. The outlook is favorable for a thriving industry in marble exportation to be opened in this country in a year or two.

A NEW AMERICAN BOOK

—ON—

Minerals, Mines, and Mining

A PRACTICAL MANUAL OF MINERALS, MINES, AND MINING; comprising suggestions as to the localities and associations of a large number of the useful minerals, full description of the most effective methods for both the qualitative and quantitative analyses of each of these minerals, and hints upon the various operations of mining, including architecture and construction. By Prof. H. S. Osborn, LL.D., author of "The Metallurgy of Iron and Steel," illustrated by 171 engravings. In one volume, 8vo, 367 pages. Price \$4.50, by mail, free of postage, to any address in the world.

CONTENTS.—PART I. MINING, MINERALOGY, AND ECONOMIC TREATMENT AND HISTORY OF THE USEFUL MINERALS. Mining, Mineralogy, Preliminary Principles and Preparations, Economic Treatment and History of the Useful Minerals, Gold, Silver, Copper, Nickel, Iron, Tin, Zinc, Lead, Manganese, Platinum, Iridium, Mercury, Antimony, Bismuth, Chromium, Cobalt, Corundum and Emery, Pumice Stone, Infusorial Earth, Grindstones, Buhrstones, the Diamond.

PART II. MINING WORK AND ARCHITECTURE, INCLUDING VARIOUS STATIONS, WITH DESCRIPTION OF ASSOCIATED APPARATUS AND MACHINERY. Mining Construction and Machinery. [This part comprises 90 pages, illustrated by 155 engravings, with details too full to be comprised within the limits of this advertisement.]

APPENDIX. Sinking Artesian Wells, Oil and Gas Wells, Index.

An illustrated Circular, 4 pages, 4to, giving the full Table of Contents of this volume, will be sent free of postage to any one in any part of the world who will apply by letter.

The above or any of our Books sent by mail, free of postage, at the publication price, to any address in the world.

Our New Revised Descriptive Catalogue of Practical and Scientific Books, 87 pages, 8vo, and our other catalogues and circulars, the whole covering all of the branches of Science applied to the Arts, sent free, and free of postage, to any one in any part of the world who will furnish his address.

MINING

—AND—

Ore Dressing Machinery.

By C. G. WAMFORD LOCK.

CONTENTS.—Motive Power.—Transmission of Power. Quarrying.—Prospecting, Shaft-sinking, Coal-cutting, Pumping, and Ventilating Machinery.—Lighting.—Hauling and Hoisting Transport.—Reducing.—Dressing.—Miscellaneous.

Price \$21.00. Circulars and Catalogues on application.

E. & F. N. SPON, Publishers,

12 Cortlandt St., New York.

A LIBRARY FOR \$1.00

Five books in one. Worth its weight in gold to every mechanic. The very latest information for 20 different trades. This wonderful book contains 575 pages absolutely teeming with rules, tables, secret processes, and new information that cannot be had elsewhere for less than \$25.00. The Model Steam Engine—How to Read an Indicator—The Westinghouse Air Brake—Blacksmith's and Machinist's Tools—Practical Mathematics Simplified—Tin and Sheet Iron Workers' Manual—Carpenter's Manual—Points for Painters—Magnetism and Electricity—How to Get a Patent—A Mechanical Dictionary. Everything fully explained in one handsome volume and guaranteed to be absolutely correct. Send \$1.00 for a copy bound in silk cloth, or \$1.50 for Morocco binding. With each copy of the book we give free a complete working chart for setting gear teeth. The regular price of this chart is \$1.50. AGENTS WANTED. Write for terms.

**Dewey & Co.'s Scientific Press
Patent Agency.**

OUR U. S. AND FOREIGN PATENT AGENCY presents many and important advantages as a Home Agency over all others, by reason of long establishment, great experience, thorough system, intimate acquaintance with the subjects of inventions in our own community, and our most extensive law and reference library, containing official American and foreign reports, files of scientific and mechanical publications, etc. All worthy inventions patented through our Agency will have the benefit of an illustration or a description in the MINING AND SCIENTIFIC PRESS. We transact every branch of Patent business, and obtain Patents in all countries which grant protection to inventors. The large majority of U. S. and Foreign Patents issued to inventors on the Pacific Coast have been obtained through our Agency. We can give the best and most reliable advice as to the patentability of new inventions. Our prices are as low as any first-class agencies in the Eastern States, while our advantages for Pacific Coast inventors are far superior. Advice and Circulars free.

Niagara Water-Power.

EDITORS PRESS:—In your issue of the 11th inst. you give me the credit of preparing the plans and specifications submitted by the Pelton Water Wheel Company before the London commission in February last, and on which were awarded the only prize coming to the United States.

I cannot claim the honor you name. My part in the matter was merely advising, and perhaps chiefly in urging the Pelton Water Wheel Company, at the beginning, to compete in this important matter. I saw from the first that the Girard type of turbine would be the only European one successfully presented before the commission, and as the Pelton water wheel occupies here the same relation to general water-wheel practice that the Girard tangential wheels do in Europe, it was the only type of wheel made in this country that could compete under a head of 140 feet.

This conjecture has proved true, and had it not been for the tender of the Pelton Water Wheel Company this country would have been in the humiliating position of having no recognition before the London commission.

The plans and specifications were the work jointly of the staff of the Pelton Water Wheel Company, who designed the wheel and hydraulic apparatus, and Mr. Hans C. Behr of this city, who designed the gearing and apparatus of transmission. My own part consisted mainly in consulting with the president and manager of the company, and in explaining, so far as some knowledge of the matter would permit, what the nature of the competing water wheels would be. Yours respectfully,

JOHN RICHARDS.

JOHN W. QUICK, Proprietor

Books on Working Ores.

By GUIDO KUSTEL, M. E.

ROASTING OF GOLD AND SILVER ORES (Second Edition) and the Extraction of their Respective Metals without Quicksilver. By GUIDO KUSTEL, M. E. 1880.

This rare book on the treatment of gold and silver ores without quicksilver is liberally illustrated and crammed with facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe, and the why and wherefore. It contains 156 pages, embracing illustrations of furnaces, supplements and working apparatus. It is a work of great merit, by an author whose reputation is unsurpassed in his specialty. Price, \$3, coin, postage free. Sold by Dewey & Co., Publishers, 220 Market St., San Francisco, Cal.

By C. H. AARON.

AARON'S LEACHING GOLD AND SILVER ORES, the most complete hand-book on the subject extant; 164 pages octavo. Illustrated by 12 lithographic engravings and four wood cuts. Fully indexed. Plainly written for practical men. In cloth, \$2. Sold by DEWEY & CO., S. F.**The Explorers' and Assayers' Companion.**

A Third Edition of selected portions of the "Explorers', Miners', and Metallurgists' Companion."

A practical exposition of the various departments of Geology, Exploration, Mining, Engineering, Assaying, and Metallurgy. Price, \$5.00 post-paid. Sold by Dewey & Co., Publishers, 220 Market St., San Francisco.

By J. S. PHILLIPS, M. E.

The work is divided into four parts—Rocks, Veins, Testing and Assaying. The geological chapters are intended to give miners a practical idea of the various formations. The chapters on mineral veins are derived from long observation, and the section on exploration has been carefully considered. All that relates to discrimination and assay of minerals has been kept as free from formulae as possible. This work is written for practical men, and all the explanations and descriptions are clear and to the point. It is so prepared that it is useful to unsuited men as well as scientists.

THE AIR BRUSH

Applies liquid pigment by a jet of air. Highest awards Franklin and American Institutes as a legitimate art tool. Successfully used by large numbers of the best crayon, ink and water-color portrait artists, and by technical draughtsmen. Saves 75 per cent of time in shading.

PERSPECTIVE VIEW OF LEAD SMELTING FURNACES SHOWING ARRANGEMENT OF FLUES.

The Late Prof. John Le Conte.

Prof. John Le Conte of the University of California died at Berkeley, on Wednesday, aged 73 years. He was only sick a few days, his death resulting from a gripe, complicated with pneumonia. Prof. Le Conte was born in Liberty Co., Ga. After receiving his preparatory classical education at a private school, under the tuition of the Hon. A. H. Stephens, he entered, in 1835, Franklin College, University of Georgia, and was graduated with high honors in August, 1838. He immediately entered the study of medicine, and in 1841 received the degree of M. D. from the College of Physicians and Surgeons, in the city of New York. In August, 1846, he was elected to the chair of Natural Philosophy and Chemistry in Franklin College, his alma mater. This position he resigned in 1855 to become Lecturer on Chemistry in the College of Physicians and Surgeons, in the city of New York. In the spring of 1856, at the conclusion of his course of lectures in New York, he accepted a call to the South Carolina College at Columbia, where he had been unanimously elected to fill the chair, then

first created, of Natural and Mechanical Philosophy. This office he held until 1866, when the South Carolina College was reorganized and transformed into the University of South Carolina. Under the new organization he was unanimously elected to the chair of Natural and Mechanical Philosophy and Astronomy. This position he held until his removal to California. In November, 1868, he was elected to fill the chair of Physics and Industrial Mechanics in the University of California, then in the infancy of its organization. Before the first officer elected by the Board of Regents, he was summoned to California early in 1869 to assist in the organization of the new University. In June, 1869, he was appointed Acting President of the University, drew up its first Prospectus, including a Synopsis of the Course of Instruction, and in September, 1869, initiated the exercises of the University at Oakland, with about 40 students. He continued to act as President until the election of President Durant in August, 1870. After the resignation of President Gillman in March, 1875, he was again appointed Acting President, and on the 1st of June, 1876, was elected full President. He continued in this practice for a year and a

half and then returned to the Chair of Physics.

Prof. Le Conte has published many contributions to medical and physical science. He was a member of the National Academy of Sciences, the American Philosophical Society of Philadelphia and of the California Academy of Sciences. The honorary degree of LL.D. was conferred upon him by the University of Georgia. Prof. Le Conte was one of the most prominent scientists in this country, and a man of high character and ability. He leaves a wife and one son, L. J. Le Conte, a civil engineer, residing in Oakland. His brother, Joseph Le Conte, has been long associated with him as a professor at the University.

Collecting Flue Dust.

We present on this page an engraving of one of the very first smelters started in Leadville, being located on the northern bank of California gulch, and although it may not compare favorably with the later smelting plants, yet it rendered valuable and effective service, not only in the way of profits, but in the development of that wonderful mining district centering at Leadville, Colorado.

As will be seen in the engraving, the flues connect the stack of furnaces with the dust-chambers, they being located immediately outside of the main building, this being the only arrangement of this kind in Leadville. The upper part of the stacks of the furnaces are connected by means of the sheet-iron flues, with a main sheet-iron flue, which enters the brick dust-chambers. Each of the flues is provided with sliding doors, placed on the upper part of the flues and parallel with them; being used for cleaning out the dust which accumulates periodically in the flues. Immediately at the rear of the dust-chamber are long rows of ore bins, and directly back of them is a large roasting-furnace. The level right above and at the rear of the roasting-furnace is the fuel level, which communicates with the blast furnaces by means of an elevated platform, provided with a track of rails. The fuel, charged in light, sheet-iron mining-harrows, is thrown down next to the feed holes along the chutes. This arrangement is capital, and saves much labor; two fuel-men only being needed to supply all the fuel needed in smelting. This is one of the first plants put up in Leadville.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—Eds.

El Dorado County Mines.

[From Our Traveling Correspondent.]

EDITORS PRESS:—El Dorado is very generally known as the county in which Marshall (at Coloma) first discovered gold. From that date until the present the hills and gulches have continued to send out a large amount of the noble metal. Mining operations at the present time are conducted so quickly that the outside world is deceived into believing that El Dorado is worked out, if not abandoned. This, however, is not the case. While the mines of the county have not attracted the capital needed to develop and equip the well-known quartz mines, still sufficient work is being done at this time to show conclusively that with capital and competent management a vast field for profitable quartz and drift mining can be developed.

Georgetown.

Georgetown has long been famous as a pleasant mountain summer resort, with excellent hotel accommodations. At this time all interest is centered in the new and promising discovery.

The Van Mine.

The Van is situated one mile north of Georgetown, in the center of an old placer mining section, which no doubt received a large share of its gold from this extensive vein. This property is in charge of Mr. P. P. Fischer as superintendent.

The mine consists of two locations each 600x1500, or 600x3000 in all. The owners are sinking a shaft, which is now down 75 feet. From this shaft a drift has been run that shows the vein to be 32 feet in width at this point. A drift has been run into the hill for a distance of 45 feet, showing the vein matter to be of decomposed granular quartz intermixed with talc and porphyry, with slate walls, the present plant consisting of a five-foot Huntington mill with a capacity of 20 tons a day. It is but a prospecting outfit to determine the value and extent of this vein. So far the vein matter has averaged about \$8 to the ton, which is an unusually large showing for a 32-foot vein. Numerous open cuts and shafts on the course of the vein show the pay to be continuous throughout the entire length of the 3000 feet. The owners are very conservative, and until the vein has been given a more thorough test will not consider themselves prospective millionaires.

Garden Valley.

The Taylor mine is situated three miles west of Georgetown, and is on the county road, midway between Garden Valley and Greenwood. This property is in charge of Mr. E. W. Chapman. The mine is opened by a shaft to a depth of 500 feet, with drifts run 450 feet on the vein.

The vein is from six inches to 30 feet in width, and is beyond doubt on the "Mother Lode." At present the work is all of a developing character. The entire output is milled, as the cheapest way to handle it; in consequence this mill value has been low. The mine is equipped with a complete 40-stamp water-power mill, with 40 feet fall for water pressure. Once the mine is thoroughly developed, and all the stamps set to dropping on good ore the Taylor will speak for itself.

Lone Jack.

A. Lawrens is superintendent of the claim. A crosscut has been driven from the 100-foot level, 80 feet to the footwall and a drift run 200 feet, showing seven feet of vein matter, the mill being hung up during the development of mine.

The Ivanhoe.

Is owned by H. W. Russel. This property is opened by a shaft on the hanging-wall to a depth of 200 feet. Had a crosscut to the footwall been run from this depth, the miners would, no doubt, have been rewarded by a vein similar to the Lone Jack. Instead a drift was run into the diorite hanging-wall for a distance of 50 feet, and the work stopped. The shaft was filled with quartz to a depth of 45 feet, when the vein matter left the hanging-wall, crossed over and down on the footwall. The shaft was continued in the gangue of the vein. As the veins of this section are very wide, it is an easy matter to be deceived, and without cross-cutting, believe that the vein has given out. But the mother lode does not give out at 200 feet on the Ivanhoe or any other mine, and this property only wants a crosscut from the bottom of the shaft to the footwall and a drift run on the vein to show it up. I believe it will prove a valuable mine from the fact that all the quartz extracted from this shaft goes over \$8 to the ton. In addition to this shaft other short shafts and crosscuts have been run on the vein all along its course, showing the vein to be strong and well mineralized.

This mine can be purchased for a nominal sum, and is an exceptional chance to get a good mine, with a small amount of additional development.

The Rozsnerans and Esperanza mines are idle at this time; the Rozsnerans awaiting

developments on the Taylor which it adjoins, and the Esperanza a mill to work its large vein.

Kelsey—The Dalmatia Mine.

The American River Syndicate Limited, John Taylor and Sons Managers, London Eng., J. Collen Pearson, resident manager, are operating the Dalmatia mine. W. H. Hubbard is superintendent. The company's mines are located seven miles north of Placerville and one mile east of Kelsey. The mine is opened by a long open cut, out of which the ore is quarried and shot down through chutes into the bins below. From these the ore is taken by car through a tunnel to the mill. The vein matter is somewhat of a conglomerate character on the surface, being composed of quartz and metamorphic slate. In the shaft which is now down 200 feet, the vein is well defined, 20 feet in width, with the quartz carrying a good percentage of galena sulphurets in addition to the free gold; 32,000 tons of ore crushed show an actual cost of 50 cents a ton for mining and milling; a record not equalled. This exceedingly low cost of working is due to the size of the vein, the ease with which it is mined and more particularly to this plant.

The mill has ten stamps and three Huntingtontons with an average crushing capacity of 3500 tons a month. In its motive power this mine enjoys the distinction of being the only mine in the State with

Electric Motive Power.

The mine is not only the pioneer in the use of electric power for mining purposes, but carries its electric power a greater distance than any other mine in America. The company owns the water rights of Rock creek on the American river, where the electric power station is situated. The electric plant at this station consists of one generator of the Brush system of 100-horse-power. The generator is driven by a specially constructed seven-foot Pelton wheel capable of working up to 125-horse power, and using 400 inches of water with 110 feet of pressure. The company has a large excess of power and can operate 1000-horsepower, if desired. The power here generated is carried within a fraction of two miles and to an elevation of 1400 feet by No. 3 insulated wire supported on poles, 100 feet apart.

At the mill the wires connect with a dynamo working up to 60-horse power, which drives the entire plant. In addition to the power furnished the mill, the electric plant also lights the mill and works by a system of seventy 15-candle lights. The Dalmatia uses but one-half of the present available power. To utilize the excess, the syndicate is about opening a mine five miles distant from the power station. At Rock creek this mine will be connected with and operated by the present electric plant. Having proven the electric system a success the company will now increase the power to a sufficient degree to enable it to work all the mines within a radius of 12 miles of the generating plant. This entire plant is connected by a telephone system, thus bringing every part of the property under the immediate control of the superintendent. The electric plant is here a pronounced success, not only does it do all the work required of it, but it almost runs itself. At first it was supposed that an electrician would be required, but at present the management and superintendent find themselves able to operate the entire plant.

This successful application of electricity to mining is not only a honor to Dalmatia, but it opens up an unlimited field of profitable mining in sections where, on account of the inaccessible situation of the mine or the absence of fuel, or water under pressure, it was heretofore impracticable if not impossible to mine to a profit.

Messrs. Jno. Taylor & Son are the largest English mining operators, and with Mr. Pearson as manager it was only a question of can it be done? Once that fact was proven, the electric plant was a foregone conclusion. The company deserves the success that has crowned its efforts, and the writer wishes it a continuation of the same.

Placerville.

At the Pacific, this work is now confined to the drifts from the 1000-foot level, which are steadily being driven ahead. In the meanwhile, the mill is idle. The Gentile Annis is running right along, dropping her ten stamps. The Big Tunnel M. Co. is running its mill on custom rock from the surrounding prospects. The Green Mt. Cement Gravel is running ten stamps. The Chill Ravine mine is now opened by tunnel 1000 feet long, and has a body of cement that goes \$2.50 a ton. The owner, Mr. L. Laudecker, is now putting up a ten-stamp mill. The Llanos M. Co., in Cedar Ravine, have their cement gravel mine opened by a tunnel 4000 feet long, and are running ten stamps. The Rodgers on Smith's Flat is dropping ten stamps on cement gravel that goes from \$3 to \$8 a car.

El Dorado.

The Church G. M. Co., Jas. Richard's superintendent, joins the old Church Union or Springfield mine on the north. At present the shaft is being put down from the 650 to the 750 level. A drift has been run from the 650 level for a distance of 87 feet, which shows a vein that averages 87 feet in width and carries 1½ per cent of sulphurets averaging \$175 to the ton, with the vein averaging \$20 a ton. When the size of the vein (eight feet) is considered, this is an exceptional mine. The large amount of amalgam cleaned up and in sight at the time

of my visit proved the ore's value. The mine is equipped with a ten-stamp mill. Once the Church is thoroughly developed, this mine should keep 30 stamps running, and thus make a record as a gold-producer.

The McNulty.

This property, of which R. S. Raw is superintendent, is now known as the Oakland. It is situated south of the old Church Union. At present drifts are being run to cut the west ledge. This vein has not been worked heretofore. The mine has a ten-stamp mill.

Los Padre.

J. M. Vandersgraff is owner of this mine. It is situated on the North Fork of the Cosumnes river, three miles south of the Church mine. The mine is opened to a depth of 60 feet, showing a 3½-foot vein of \$13 ore, and is equipped with a five-stamp mill. The shaft will be put down 100 feet this season and levels run.

Slate Mines of El Dorado Co.

El Dorado county claims to produce a quality of roofing slate not excelled by that from any other section. This slate deposit is very extensive. Near the Church mine at El Dorado, excellent slates, crops, and as you go north from Placerville to Kelsey, the whole section is slate. The mountain on which the quarries are being worked is known as Slate mountain.

The Jacob Strahle Slate Co.

J. Strahle is superintendent of this quarry, which is near Kelsey. The mine is opened by three faces, and is now taking out 200 to 250 squares a month. The output last year was 1000 squares. Once the mine is opened and benches secured, the output will be increased from 500 to 1000 squares a month. This quarry has furnished slate for the Deaf and Dumb Asylum at Oakland, Concordia Club House Van Ness avenue, S. F., and is now shipping to the Ukiah Insane Asylum and to other places. Mr. Strahle has under construction a narrow-gauge railroad to carry his slate to Chili Bar and thence to Placerville. With water for motive power, this, when completed, will bring all of this freight traffic from Kelsey to Georgetown over this line, and save the climb up the mountain from the American river.

The California Slate Co.

This quarry (E. Bird superintendent) is located on the north side of the American river. The property consists of 640 acres. The slate is opened up by a face 120 feet in width, with three galleries, each of 40 feet. The quarry's output is 200 squares a month. The company now intend to increase their capital stock \$25,000, and with this amount increase their facilities, so that they can keep up with their order. This company has furnished slate for roofing the Stockton Courthouse, State Asylum for the Feeble Minded, Glen Ellen, S. P. R. R. Co., and numerous other parties. In the past year, the company produced slates to the value of \$10,000, and now has orders ahead for a year's output.

Chili Bar Slate Quarry.

Geo. J. Mothershead is superintendent and owner of the Chili Bar quarry, which is situated on the south bank of the American river, three miles north of Placerville. This property consists of 40 acres—all solid slate. The mountain has here an almost perpendicular elevation of 700 feet, affording unusual facilities for rapid and cheap extraction of the slates. The quarry is opened by two galleries of 40 and 60 feet. At present the output is 100 squares a month (ten feet finished on the roof is a square). The slate brings \$7 a square on board cars at Placerville. The Chili has produced \$16,000 worth of slate in the past year, and has now orders ahead for several months. Among its customers are the asylum at Glen Ellen, S. P. R. R.; Lick Baths, S. F.; Deaf and Dumb Asylum, Berkeley; and Napa Asylum. This quarry's slate was awarded the first prize at the Mechanics' Fair in 1890, in competition with all of the slates quarried in the State; also the first premium each year at the El Dorado County Fair. If these slate quarries were located in Pennsylvania, there would be a rush of capitalists to secure them. The supply is practically inexhaustible; the situation such that the slate can be quarried out at a nominal cost for a century to come. What the mines supply is far in arrears of the demand. All that is wanted is the necessary capital to open, equip and extract the slate. Capitalists will find this an unexplored but most profitable field for investment, either to purchase the quarries now being worked or to open and develop new properties. In time El Dorado county's slate mines will crowd her quartz mines for supremacy.

E. H. SCHAEFFLE.

Murphy's, Cal.

Loss of Gold in Milling.

Experience in Colorado.

EDITORS PRESS:—I have read with a great deal of pleasure at different times the able articles by Mr. A. B. Paul, especially in your issues of April 11, the article on "Loss of Gold." We have always looked upon California mining and milling to be away ahead of Colorado, but if such losses exist as Mr. Paul states I think we can beat them. Of course, to amalgamate, we do not use the fast drop stamp, as we found it quite out of the question. As an illustration I will give the work of my own mill which is considered by all to be the neatest, best crushing and best mill in the State, in fact its considered

a model mill, and has been extensively copied after, but I am free to state not with the same results as to work. Perhaps the secret lies with the millman as we find very few who are willing to conform to modern uses. Nineteenth of them still stick to the old first principles. I have a 680 lb stamp that drops 18 inches and 29 drops a minute; each stamp crushes a fraction over a ton to the stamp in 24 hours through a 50 mesh flat punched screen. The rock is above the average in hardness and very heavy in mineral such as pyrites lead and zinc with some copper. Out of four tons of ore we get one ton of concentrates. The ore is broken and fed by hand, feeding very low in the dies. Silver plated coppers are used in battery and outside thence to blankets and from there to one of the best little machines ever built called the Gilpin county bump-tables which is about six feet long and three wide. This easily handles five tons every 24 hours and on exhaustive tests of all kinds of ore beats them. The price of this table is but \$100. It is simple and easy to handle and when once adjusted requires but very little attention. Frequent samples are taken from the tail of this table every hour and allowed to settle; then dried and assayed. Such small loss is shown that blankets, after these tables, were found to be of no use. We have had frequent tests of ore taken to our sampling works, crushed, sampled and assayed, and then brought to my mill which showed a saving of 85 to 90 per cent of assay value. Also the getting rid of 700 lbs of zinc in one lot which is a detriment to the concentrates for smelters.

This I know Mr. Paul will admit is a very close saving. After 20 odd years at the business I have come to this conclusion; a certain percentage must go to waste. We rich nature, she is but taking back a little; to reduce it down, get a mine with favorable ore. I am free to say, I am not particularly stoked on the noisy stamps and the constant splash, and realize that nothing can beat the old time arrastras. The Risdon Iron Works of your city are building my ideal of a mill or what I should call an improved arrastra in the Bryan Mill. It would be a great hit if your State geologist would take this matter up and devote part of his most excellent annual report to the different milling plants, and give us figures upon these different kinds of mills. A full discussion by millman on this most important of subjects, cannot but prove a great boon to this great and growing industry. When you get about 85 per cent on assay value in milling, the proof has got to be as awful strong for one to swallow it. What does Mr. Paul think?

PHILIP MIXSELL.

Idaho Springs, Colo.

The Mining Business.

D. W. C. Morgan, who has for many years been connected with mining, remarked yesterday that a few observations on the subject might very appropriately come under the head of "Chat on 'Changes.'" "Unless," continued Mr. Morgan, "it is no longer considered a business in California, and one would very often think so from the difficulty experienced in raising the necessary capital. It was not always so, and it is not likely to be so in the future. The gold deposits of the State are of too much importance to this world at large to remain uncovered."

"In the eternal strife designated as 'business,' the man who makes profits without making them out of their fellow-men are the real producers. The miner who digs a ton of silver or gold-bearing ore adds its value to the wealth of the world without taking anything from any one. He opposes no man, feels no heart burnings from the opposition of any other person because no opposition reduces his profits, or interferes with his business, and for the reason that in all these respects he is a public benefactor, he should have the goodwill of all. His success means benefit to every human being in the land. His is a business which gives full scope and chance for the development of all good and generous impulses, unchanged by the forces of every jealousy and strife, culminating in an everlasting attempt to get the better of 'this other fellow,' and it makes the miner the whole-souled, generous man that he is."

"The mining interests of California have been sadly neglected during recent years. Stock speculation in the Nevada silver mines and wild cat propositions all over the country have had an unhealthy effect in poisoning the public mind against legitimate business. The very mention of a mine is obnoxious to a man who has dropped money in some venture, where all the salvaging done was in the pockets of stock holders through a stock exchange. These people know nothing about real mining, and they do not care, as a rule, to have it explained to them. This explains the reason why English companies like the Sierra Buttes, and others have been able to take their millions out of the country. They had the grit to invest in a mine which repaid them handsomely."

"The same might be said of the neighboring States and Territories. Our people had the first offer of everything valuable there, but it was quietly passed into the hands of Eastern men, who are now reaping all the benefits. When the same people begin to fully understand the profits which accrue from gold quartz mining in California, history will probably repeat itself, and mines which should be held here will be controlled in Chicago, Boston and St. Louis.—S. F. Post."

Blue Gravel in Siskiyou.

Mr. C. B. Jilson writes as follows to the Yreka Journal:

There has been a great deal said about blue gravel. I have probably said less and done more toward developing the blue lead in Siskiyou county than any other one man. I have traced this dead river channel from Butte county to and beyond the Oregon line. There is, however, much country between here and Butte which I have not traversed, and there may be places with equally as good facilities for working as we have here, but I know of none. Pressure, grade and dump are unobscured, with the Klamath river to furnish unlimited power for electric motors, lights, etc., while accessibility could hardly be improved upon, situated, as we are, only two and one-half miles from the railroad depot, with a good county road passing over the mine and directly in front of our door. Perhaps a synopsis of what I have been doing shows my advent into Siskiyou county might prove interesting to your readers. In June, 1887, I came to Henley and located, to my entire satisfaction, two miles of the Blue Gravel mine, before striking a pick into the ground. That summer we ran 370 feet of tunnel, and found the bed-rock pitching, but were rewarded by finding ground that paid, for the last day's work done in the drift, \$30 to the pick. In December, I moved my family here. We then went 1000 feet nearer the river and ran in 190 feet, and, in this drift, found gravel that will pay from five cents to \$3 to the pan. One of the most serious obstacles to overcome was to obtain water. W. H. Smith owned and controlled all of the water in this section, and his property being bonded barred all negotiations until after the expiration of his bond in November, 1888, when we purchased one of his rights for the sum of \$6000. We then had nearly seven miles of ditch and flume to build, which carried us into the spring so late, and being an exceedingly dry year, were unable to do anything but a little prospecting, so that last season was the first opportunity we had of making a showing, and that was mostly consumed in opening the mine, leaving us scant two months to work ground from which we could expect any pay. But few of the citizens of Henley and vicinity had any faith in the enterprise, some of them telling me there was nothing here, that it had been thoroughly prospected 30 years ago; while others went so far as to say that Jilson was an impostor, working a scheme upon the credulity of his friends to obtain money. He, however, kept on the even tenor of his way, his son, son-in-law and self owning and paying three-fourths of the total expenses.

It was only a repetition of history. A new departure for the time being creates antagonism in any community. They are now all enthusiastic over the good find, and gladly acknowledge their belief in the blue lead, and that it is destined to add immense wealth to Northern California. I notice that some correspondents claim that it is impossible to tell the extent or width of the channel east, as at no place is the rim to be seen. From past experience of ancient channels, it is not presumable that the pay will exceed 400 feet in width. As to the east rim, it is just as plainly to be seen at the south end of the Blue Gravel mine as is the west rim, and from rim to rim the distance is about 1200 feet, the sand rock sitting directly down upon the east rim. At no place in this section, north or south of the Klamath river, does the east rim show, from the fact that it is capped with overlying sandstone, the same as the channels in Sierra, Plumas and Nevada are with lava. The Black Jack Company are working very hard cemented gravel, a secondary or later deposit than that of the Blue Gravel Company, from the fact that it has corroded and been carried away from the Klamath river to the Rocky Gulch. If they would not go down, they would find the gravel free and bedrock soft, the same as the Blue Gravel Co. has. The latter company has been doing fair work since the first of March with a light head of water, at no time exceeding 400 inches in their ditch, but reserving enables them to pipe nearly one-half of the time. They are running their main tunnel night and day and expect to be into pay about the first of May, and within six months will probably employ 75 or 100 men, to add on thereafter as room is opened. The cold weather is favorable to the miners, but at heat the season must be short. The El Dorado and Ashland Company hored to bedrock, at a distance of 160 feet last fall, with satisfactory results. A Portland company is at present sinking a shaft north of the Black Jack Company. Owing to facilities for working, I consider that B. Hickox of Oakland and Capt. Welbourne of this place have the second best location in this section. There are locations on all sides of us, north, south, east and west, and however much we may wish it, it would be a miracle for them all to make a strike. Those who have locations upon the channel have mines to develop. Those with locations off the channel have mines—to find.

"THE SHEFFIELD OF SWEDEN."—The Swedes have become very skillful in the manufacture of cutlery. The town of Eskilstuna, lying not far from the western end of Mälar Lake, is now widely known—and deservedly so—as "the Sheffield of Sweden." Here are situated a dozen or more factories, which turn out the

finest cutlery and tools. Eskilstuna razors, pen-knives and scissors are well known and highly prized in almost every country of the globe.

Our Bargain with the Inventor.

A United States patent is a contract. The parties to it are the inventor on the one hand and the people of the United States on the other. The inventor, by a public record, informs the people concerning a useful discovery which he has made, which must be original with him and new in the United States. In return, the people, by their letters patent, secure to him the exclusive right to make, to use and to sell his invention for a limited number of years. At the end of that period the contract terminates, and the discovery belongs to all the people forever. A patent, therefore, does not flow from the bounty of the community as a pension, or a subsidy or a medal. It belongs to the inventor by right. It comes into existence in consequence of the legal establishment of a certain state of facts, namely, that the invention is new, useful and original with the claimant. This disclosure is the consideration on the part of the inventor, who, therefore, gives the community something of value which it did not before possess. The community gives to the inventor, not something of value which it already had, as where a part of the public domain is patented to a settler, but simply protection. If the invention is valuable, so is the protection; if the invention is worthless, the protection is without benefit. Thus the contract is reciprocal and evenly balanced. The validity of a patent depends upon the maintenance of the facts established. To determine issues of validity is a function of the United States courts; to determine whether the consideration probably exists, and to make the contract itself, is the function of the United States Patent Office. "He who receives an idea from me," wrote Thomas Jefferson, "receives instruction himself without lessening mine; as he who lights his taper at mine receives light without darkening mine." An idea once made known is subject to human control only when incorporated, and therefore it can become the subject of patent only when it is tangible and existent. In the beginning it may be regarded as a marvel; in time it becomes a necessity of life, a manufacture, perhaps the basis of a great industry. In a certain sense the invention then detaches itself from the inventor, for the patent no longer protects only one man, but through him many men in their rights.

The patent system of the United States has now completed its one hundredth year. The experience of the century shows that the advantages incident to the patent contract constitute a sufficient incentive, not merely to lead people to publish their inventions, but to make them invent. The number of patents granted yearly has steadily augmented; it is now more than 25,000 and is increasing. Under the fostering protection of patents we have developed, and are developing inventors as a distinctive national product; and because of this we are enabled to exhibit to the world a growth and prosperity as a manufacturing people unexampled in the history of mankind. The patent contract secures to the inventor his right for a fixed period of time, absolutely and without limitation, save by the obligations which every man owes to society. It assumes that self-interest will best conduce to the development of the invention, and therefore, it imposes on the patentee no recurring taxes, nor does it compel him practically to operate his device. A patent grant is not made in payment for an invention, in the sense that one is a measure of value for the other, but in return for its disclosure. No one can assess the value of a new discovery to the human race for all time. The more important it is, however, the more income must become the returns obtainable during the latent period. The millions made from the patents on the sewing machine, or the reaper and mower, or the telegraph, or the telephone, are utterly inconsiderable beside the enormous benefits which the public acquires through all industry from these inventions. Whether the thing contrived is to underlie a great industry or whether it is merely an improved pin, the inventor, to be entitled to his patent, must disclose it fully, and without restriction or reservation; so that when the patent term shall be finished, the public may be able to make and use the thing as well as he himself can make and use it. He is entitled in return to equally full, unreserved and unrestricted protection. To lessen the enjoyment of that protection, or to limit it by harassing requirements, such as taxes or obligations to work the invention, as the opponents of the system have proposed, would amount simply to failure on the part of the people to comply with their side of the contract.—Park Benjamin in the Forum.

AGE OF THE OAK.—The heart of the oak begins to rot at about the age of 300 years. The holly oak alone escapes this law. It is said, and there is a specimen of this age 410 years in existence near Aschaffenburg, in Germany.

WOOD AND IRON WORKING MACHINERY. Statistics show that the average duration of wood-working factories is eight years and of machine-shops about twenty.

EVICCTIONS of striking miners in the Pennsylvania coke regions continue.

Asphalt in Kern County.

Mr. Louis Blankenhorn gives the Los Angeles Herald the following account of the asphalt fields of Kern county:

The mines occur in two fields, south and west of Bakersfield, one lying in the foothills on the north side of the Tehachas, and the other on the eastern slope of the Coast Range. They have been practically unknown for many years, no State mineralogist or geologist, except perhaps Hanks, having mentioned them. Their value, however, was foreseen, and the locations covering the asphalt and oil, they being together, were most of them patented years ago, among others by Solomon Jewett, the millionaire banker, rancher and sheep-raiser, who located a claim in 1861—30 years ago. The Bona Vista Oil Company spent \$25,000 in development, and the Union Oil Company, composed of Georgians, a large sum also; but lack of transportation, or high rates and prices, made it unprofitable in those times. Since then the investigation of asphalt and its application to paving, roofing, varnish and other uses have brought it into use in the United States to the extent of 70,000 tons annually, with an increase of 50 per cent last year, practically all of which has heretofore been imported. Its obsolescence has been for paving, over 400 miles of it now being laid in a score of cities, including New York, Brooklyn, Philadelphia, Washington, Buffalo, Cincinnati, Detroit, Omaha and St. Louis, on a large scale. It is looked upon as the most desirable pavement from the standpoint of durability, cleanliness, noiselessness and economy ever used by cities, and the demand for it in the immediate future is likely to take the world's sources of supply.

California is the only State in the Union today which gives promise of any ability to fill any portion of the demand. Although asphalt has been found in Utah, Wyoming, Kentucky, and other localities, its development has been hampered by problems of distance, transportation, etc. It is found in various counties of the State, from Monterey south along the Coast Range mountains to Los Angeles, but I believe it is reserved for the Kern county fields to show a future production of millions of tons, and a supply second only to the pitch lake of Trinidad.

The two fields mentioned are each about five miles long, and the black surface indications, outcrop and springs in many places still alive are visible for miles when approaching them. The Standard Asphalt company, of Bakersfield, Cal., now controls these asphalt mines, and for several months past have been engaged in refining and shipping it. Some of the men constituting the company, bringing to it the capital and experience necessary to push it, are Solomon Jewett and H. A. Blodgett, of Bakersfield, Henry Williams of San Francisco, E. G. Church, for many years manager and superintendent of the Barber Asphalt company at Buffalo and Kansas City, S. Hinton and myself of this city. Mr. Church, who is an expert and authority on asphalt, and familiar with the Trinidad and others, pronounces the Standard, of Kern county, equal to any produced, if not superior, for paving and kindred purposes. The companies have now a force of men and 20 kettles in operation refining the asphalt, which refining capacity will be largely increased by plants now being constructed.

In close proximity to the asphalt fields, and a part of them, are wells, springs and tunnels producing a very heavy petroleum oil, whose base or residuum, being asphaltum, is a very valuable aid and adjunct in the fluxing and refining of the hard and rocky asphalt. This quality in this oil has given great value to a formerly almost useless form of petroleum, and is causing it to supersede for this purpose the coal-tar and residuum in universal use in the East, produced from the Eastern oils having only paraffine and no asphaltum base.

The asphalt occurs in layers and masses, at present of unexplored thickness, easily taken out with the pick and wedge. The liquid asphalt or flux is added in certain proportions, and melting proceeds until the dross or sand has settled and the pure and refined liquid can be drawn off into boxes and barrels ready for shipment. A higher degree of refining is required for the roofing compound. This compound has a flexibility at all temperatures very superior to ordinary asphalt, whose nature when purest renders it very brittle when cold and runs when warm. It is a singular fact that in California, where the asphalt has always been obtainable to some extent, roofs of asphalt and gravel or felt covering are scarcely known, while in the Eastern States, a land of very cold and hot extremes, there are veritable square miles of roof, covered with coal-tar and gravel compounds called asphalt, but concededly inferior. California should supply a great many tons of asphalt for roofing in the future. The asphalt beds of California and their products will be a mine of wealth to Kern county, and incidentally to California.

It is now extensively used in Southern California in paving for sidewalks and floors, also for the lining of reservoirs and flumes. The Los Posas Land Company and Santa Ana Water Company of Ventura county, E. L. Barber of San Fernando, J. I. Case & Studebaker of Monrovia, the Victoria Mining Company of Azusa, the Bear Valley Irrigation Company, J. D. Sobnyler, former State Engineer, and others, are cases where asphalt has been used for reservoir or flume work with most satisfactory results. This use alone means ultimately the supplanting of imported

cement and the keeping at home many hundreds of thousands of dollars now sent abroad, aside from the possible construction, cheaply, of reservoirs in situations not possible with or without cement.

Kern county has vast mineral resources aside from its wonderful asphalt. I saw on the same quarter-section with the asphalt beds, oil springs and oil-producing wells, a tract measuring many acres, seemingly, a crust of sulphur in several places developed thus far four to six feet deep, by analysis 80 per cent pure; kaolin strata two feet thick, white, soft and fireless, producing, it is stated, by analysis, 35 per cent of aluminum; and in the same strata crystals of alum seemingly pure when tasted. In the mountains near by are known to be silver, antimony, tin and iron, while gypsum is widespread in its showings. Mr. Blankenhorn brought home specimens of many of these articles.

Prospecting a Mine.

The Virginia Enterprise says:—The statement that the Comstock lode has been pretty well prospected below the water level to the depth of over 3000 feet has often been published by journals in the East that devote some attention to mining and it is generally believed by the readers. The statement is absolutely false and works great injury to our industry.

In the Gold Hill mines a long drift was sent out on the 2700 level of Crown Point, which struck an immense flow of water that came from the Eschequer ground. It also struck a rich body of quartz which the mine management would have given a great deal of money to have been permitted to prospect, but the water drowned them out. When the water was struck, prospecting drifts had entered another promising body of ore on the 2700 level of Belcher. They were driven from that, and it remains unprospected. On the 1900 level of Crown Point, and also on the 2200 level, there are two bodies of ore known to exist, where the miners were driven by the flood, but the Gold Hill pumping operations will soon regain possession of the country to that depth.

As depth was attained during deep mining on the lode, long drifts were speedily shot out from the sinking shaft stations, but no time was allowed for proper prospecting work, such as any recently informed miner would call prospecting a mine—such work as is now being done in the upper levels.

Time and again leading Comstock mines have been on the point of being abandoned, when luckily some prospecting work being done immediately between formerly explored levels would strike ore from which millions of money were subsequently taken out. Con. Cal. & Va. sold in the open Board for 25 cents a share—and operators shorted it at that—and in an incredible short time the same shares sold at \$65 a share, and \$3,466,700 have been paid in dividends since, and at least \$17,000,000 have been taken out from what was then called a prospected mine.

James G. Fair said he had prospected Hale & Norcross, and "swept this waste with a broom." Within exactly five feet of one of Fair's prospecting upraises Superintendent Keating struck a body of ore from which about \$5,000,000 have been extracted.

Within the past few weeks in the Savage a body of rich ore was struck within a foot of an old prospecting shaft.

Still, alleged mining writers say that the Comstock lode has been pretty well prospected below the water level.

What is understood as prospecting a mine nowadays is to cut it up into 50 foot cubes by lateral drifts, crosscuts, raises and winzes, and no good miner will consider that it has been prospected until this has been done.

American Tin.

When the train bearing the Presidential party arrived at South Riverside, a novel sight was seen. Manager Robinson of the San Jacinto estate had erected on a raised platform a pyramid of tin, 15 feet high, containing 100 ingots of 64 pounds each, of pure metallic tin. The pyramid was surrounded with specimens of the ore, and bore the inscription, "The First American Tin, April 23, 1891." The stars and stripes and the company's private flag floated from the top of the glittering mass of metal.

As the train came to a standstill, the President and several of his party stepped out on the car platform to witness the novel exhibit and were welcomed by Colonel Robinson, who explained that what they saw was the first successful attempt ever made in America to produce tin from its ores in a large way, and that the mines under his charge gave every assurance of a continuation of the product. He thought that with the assistance of the McKinley tariff, in all reasonable probability, American tin mines could produce enough of the metal for the consumption of the United States, and also successfully compete with Great Britain in the manufacture of tin plate.

The president spoke briefly in reply to Manager Robinson's address, wishing success and prosperity to the enterprise in which he was engaged. Afterward President Harrison and several of his party descended from the car, and, standing at the base of the pyramid, were photographed. Each of the party was then presented with specimens of the tin and ore, after which the special train moved on amid the cheers of those assembled.—Call.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

SUTTER CREEK.—*Cor. Amador Ledger*, April 25: Operations at the North Star still continue. They are drifting in a northerly direction, and will go a considerable distance yet before they will be satisfied. There is no doubt that before the property will be abandoned, another 200 feet will be sunk, and considerable drifting done at that level. Important changes in the way of improvements are to be made in the South Spring Hill mine, between here and Amador City, in a short time. The hoisting power is to be changed from steam to water. Knight & Co. are getting out two 8-foot water-wheels to operate as a reversible power for hoisting and lowering. The steam hoist will be allowed to remain, so as to be ready for use in case of a break in the ditch or other failure of the water supply. The principal object in this change is economy. The timber is getting scarce, and wood has to be hauled from a distance, and as a result has a steady upward tendency in price. D. T. Davies, while here, ordered at Knight's foundry three 3-foot water-wheels for the Carbonado coal mines, Washington. They are to be used on the condensers in furnishing air underground. The wheels will be ready for shipment in a few days.

PLYMOUTH.—*Cor. Ledger*, April 25: The New London Co. has let off about one-half of its force of miners, so it is running the mine with about 10 or 12 men just a good prospecting outfit. The Plymouth Consolidated mines are working as usual. The mill is still running 40 stamps. Lamb and Hanna, owners of the Good Hope mine, are putting up steam hoisting works, and are going to sink 300 or 400 feet deeper, and if the vein continues good there will be a 40-stamp mill erected on the claim. The Reeves mine is idle on account of putting in some new machinery, which will not take long, when the mine will be worked for all that it is worth.

FROM PINOEER CREEK.—*Cor. Dispatch*, April 18: Pioneer and vicinity is still in a flourishing condition. There is more ore out and in sight than there has been in the last 15 years at any one time. The energy and enterprise displayed here through the last few months is almost certain to develop mines that will last for years and pour out a constant stream of the most precious metal known to commerce. On the Mokelumne river side of the ridge is situated the Strinman mine. This mine has out 700 tons of \$40 ore; the ledge, three feet wide, has a shaft sunk down 60 feet deep to water, and levels run at water level. The ledge is one mass of sulphurets which assays over \$600 per ton. At present they are milling their ore at a mill near the mine which is owned by Mr. James of Pine Grove. A short distance from here is situated the Old Bowers mine which has been reopened by Steve Werly and has every indication of contributing to its lucky owner ten fold more than his fondest expectations. About two miles south of this is the consolidated Sittling Bull. This is an east and west ledge and is owned by Lee Jones and Len Harmon. The ledge is four feet wide and prospects for about \$12 per ton and is traceable for 800 feet on the surface. There is about 75 tons of ore on the dump. West of this mine is the North Star. Their tunnel taps the ledge some 90 feet deep, and the owners, Mr. Boomershine and Strinman, are well satisfied with their prospect. The next mine below this is owned by Mr. Pine and others. This is also worked through a tunnel about 700 feet in length. At present they are sinking a shaft about midway of the tunnel. The ore in the shaft is high grade, heavily sulphureted with considerable free gold. There is about 60 tons of ore on the dump. Next comes the Marchand mine. This is also worked through a tunnel. The ledge is about two feet wide and heavily sulphureted. Mr. Marchand has been a long time getting to this ledge as the rock was extremely hard, but now he feels confident that he will be reimbursed for all his labor and outlay. High up the mountain from here is the Klamman mine. There is about 15 tons of ore on the dump with room for more. Mr. K. works alone, consequently he does not make very rapid headway, yet he has a very good prospect. From here we were soon on the ridge again where we met Mr. Harker who informed us that his youngest son had unearthed a ledge a short distance back of his dwelling house. It is about a foot wide and prospects about \$60 per ton. Mr. Kimball is still working on his mine. He has out about ten tons of ore. The mineral rod is still pulling toward the Arctics. We called at this mine but did not see any one as they all appeared to be working underground. The Griesbach Yelmini has developed into a 15-foot ledge of low-grade ore, and they have started their mill running with five stamps on their own and five on the Bowman ore. A few days ago the Gracy mine struck some extremely rich rock, but as they pushed the level ahead the ledge cooled down to its regular business.

BELL WETHER.—*Amador Ledger*, April 25: Sinking the shaft in this claim in Bright's field has progressed to the depth of 90 feet. The shaft was started on the incline of the ledge; latterly the ledge was found to turn, but the shaft was continued on the same uniform angle. It is not in ledge matter at present, although occasionally they break into quartz, which prospects well. The formation is much better for sinking than the hard quartz. Progress, however, is slow, on account of the quantity of water to be handled. Three shifts are employed, eight hours each. It is intended to go 200 feet, and explore the vein at that depth.

HARDENBURG.—The 20-stamp mill is about completed. Mr. Woodbury, the inventor of the concentrator which bears his name, came up this week to personally attend to the fixing of the two concentrators of his make to be put in this mill. It is claimed that one concentrator will be able to handle the discharge from a five stamp battery. Two Frues are required for each battery where heavy stamps are used. As the stamps of the Hardenburg are light—600 lbs—it is possible that one concentrator will do the work. The pipe is being laid from the mill to the ditch, and next week we hope to report the mill in active operation. Some 400 or 500 tons of ore lie on the dump ready for crushing.

BELMONT.—The superintendent, under date April 23, reports:—The surface tunnel is now in 265 feet, the last 100 feet being driven all in ore,

The mill is kept constantly running; the plates, both inside and out of the batteries, are yielding well.

Calaveras.

RESUMING WORK.—*Chronicle*, April 25: The Quaker City quartz mine, near the Junction, which had suspended operations for a while past, has resumed work. The water has been taken out of the shaft and the shaft repaired, and a contract has now been let, we understand, to sink 100 feet. The present depth of the shaft is 400 feet. The mine is located on the line of the mother lode. With good management, perseverance, and a fair outlay, success may be reasonably expected. The mine is under the superintendence of that efficient veteran miner, Tom Goodwin.

MINING ENTERPRISE.—*Calaveras Prospect*, April 25: The work on the mine on the San Andreas channel at the Swenson place is being pushed rapidly forward. Two steam pumps of the most improved pattern are at Valley Springs, and will be on the ground in a few days. A large force of men has been at work this week getting things ready for the machinery. A dam has been put across the creek between Mrs. Hopkins and Wylie's houses to turn the water into the old ditch, and teams have been hauling pipe and lumber on the ground.

THE PIONEER MINE AT ANGELS.—Conly and Hallock, started up Monday with work on the shaft. This bids fair to be a large addition to Angels' already large mining interest. The mine is on the Mother Lode, and is known to be good property. A 20-stamp mill is to be erected at once, and work will be pushed vigorously.

UTICA.—*Mountain Echo*, April 25: Improvements are going on constantly at the Utica mine. A large building is being erected on the north end of the blacksmith shop, which when completed, will be used as a machine shop.

El Dorado.

ST. LAWRENCE.—*Mt. Democrat*, April 25: It is generally understood that Superintendent Pierson, of the Delmatia mine, has secured the old St. Lawrence property, beyond Kelsey, and on the first of the month steps will be taken to again open up this property. The old St. Lawrence was a very rich mine, and a mint of money was taken out of it by the company formerly operating it. The mine has lain idle for many years, but has now fallen into the hands of practical, energetic men of capital, who are conservative in their movements, yet bold in action when they have demonstrated the worth of their ventures. The magnificent electric power now operated by the Delmatia company will be utilized for the St. Lawrence, and to that end the line will be extended, making a circuit of ten miles. The availability and cheapness of this power, and the amount that can be supplied, places the company in a position to work the mine to better advantage than any one else. We are confident that the managers of this property will develop a paying mine, if it is there, and if they succeed, Kelsey will be the liveliest mining center in the county. While but little has been said of the Blair mine in the vicinity of the Nine Mile House, the owners thereof are pushing the work. The tunnel started for the gravel deposit is now in over five hundred feet, and has nearly that distance yet to go. A few months more will settle the point as to the richness and extent of the paying channel. The recent finds in gravel along the ridge make almost a certainty of the supposed channel extending through the entire ridge. The late developments in the Larsen claim show a very rich channel at a point three miles below the Blair's tunnel. Mining matters therefore are looking much brighter along the entire ridge. It is reported that the old Larsson mine near Latrobe has been put into the hands of a San Francisco company to operate. In the Gray and Bosquit claim at Pine Mountain, work is being pushed ahead as fast as possible. The upraise and air shaft was recently finished, and the tunnel is being driven ahead with the vein in good rock. The mill is being put in shape, and ore will soon be crushed. There is now a large amount of high grade ore ready for the stamps. The litigation over the Toll House mine at Smith's Flat has interfered somewhat with the working of the claim, pending the settlement of the controversy. It is to be hoped that an understanding will be arrived at that will not interfere with the pushing of this work through.

PACIFIC.—The Pacific Co. is pursuing work all along the line on their claims, from the Van Hooker on the north to the Epley on the south. The vigorous work covering a wide territory has kept Superintendents Rowland and Evans pushed and on the go for some time past. The company is now keeping 40 miners employed all the time. At the Van Hooker they are driving tunnel; at the Old Harmon they are making an upraise and running levels, and have opened out a big ledge. There is a fine body of quartz visible in this mine. Work has ceased temporarily by the True Co., but will soon be resumed. At the Epley, the Pacific Co. is driving a tunnel to open the mine on the 100-foot level. The Gentle Annie mine and mill, which have been idle for some days, expect to start up again on Monday. The Rogers claim at Smith's Flat is steadily working on good gravel, and the Linden is doing the same. The Big Sandy mine at Kelsey, which has been idle for some time past, resumed work on Monday last, and is helping along the Kelsey mining boom. It was reported on the streets during the week that a fine strike had been made in the Pacific. It was well known that the shaft had been sunk to the 1000-foot level, and that prospecting was in progress on that level, a drift being driven in on the ledge. In order to determine the truth of the rumor we called on Supt. Rowland for information. That gentleman, always cautious, and reticent in discussing the affairs of the company, represents, courteously informed us that on Saturday last the workmen had encountered some very good rock in the mine on the 1000-foot level, where they had been working for some time past. As to the extent of the find, and the richness thereof he did not state, as he evidently considered they were matters concerning which the company alone was concerned. The whole community will be glad to hear that good paying rock has been found in this level of the mine, and that development work has shown there is mineral there with depth. When, during last year, the company decided to sink at once to 1000 feet, and by prospecting determine the value of the mine, the proposition was hailed with satisfaction by our citizens, most of whom believed that through prospecting would show the mineral to be there, and rich enough to pay for working. The present discovery proves the permanency of the

mine, and that depth will yield good mineral. A good vein at 1000 feet, and the immense body of ore between that and the surface, means permanency of working, and the employment of a number of men. There is probably not another mining company in the State nor on the coast possessing such a quantity of mining ground that could be worked to such advantage, and at such a small cost, as the group of mines owned by the Pacific. They occupy the main mineral belt of the country, including the "Mother Lode," for several miles north and south, having an almost continuous property. Not one of their mines but what has upon it one or more natural locations for a millsite; and every one of their claims is adjacent to their ditch and can be operated under a water pressure varying in different localities from 150 to 750 feet. With their own ditches and free water, and with every facility for economical handling of ore, this company could handle good ore at a handsome profit.

MAMELUKE.—*Georgetown Gazette*, April 23: T. LeBeuf is pushing in a tunnel on his old Mameluke ledge north of town, at a point in the canyon which will give him more than 100 feet of backs with 100 feet of tunnel. He has a well-defined lead of soft ore about 25 feet wide, on which he has run about 40 feet. The ore prospects very uniformly in free gold. About 900 feet to the south the surface of the lead had been sluiced and worked with rich returns, but work ceased on account of the large amount of water to contend with. Old-timers declare that this is still a rich mine, and that if LeBeuf can succeed in getting his tunnel in to a reasonable length he will get all the money he wants by simply sluicing the material. The mine is secured by a U. S. patent.

DEVELOPMENTS.—*Republican*, April 23: Some new developments are being made at the Gentle Annie mine and rich ore found.

Inyo.

ANOTHER DIVIDEND.—*Index*, April 22: The Newtown Mining Co., with office in Carson City and works at Cerro Gordo, Inyo Co., has just declared dividend No. 2 of five cents per share.

Mariposa.

COULTERVILLE.—*Cor. Mariposa Gazette*, April 23: The Bondurant mine is running at full blast, and is yielding good ore. Mr. S. B. Sample is still working the Black Bart, with good prospects of another pocket. It is hoped his prospects may be realized. W. Davis of San Francisco, and W. Downie of Tuolumne county, are preparing to commence work on their claim at Flyaway, about one mile from the Southern Cross. The Harrison mine owned by H. Boisse and C. L. Mast, is near the Black Bart mine. They have been running a tunnel for the past eight or ten months, and have recently struck good prospects while tapping their main shaft. The rock taken out of this mine was crushed in the Bruschi mill, and yielded \$65 per ton. The Quail mining company are running their mill, and the rock which has been run through this mill has been sufficient to purchase a boiler and engine to run during the dry season. Mr. Bruschi, the owner, is now in the city, purchasing machinery to run by steam power. The sulphurets tested from this time, averaged from \$800 to \$900 per ton. George E. Clark, one of the men who found the pocket in the Black Bart last winter, came into town on the 11th inst., with about 50 pounds of magnificent ore, which he had taken out of the claim recently purchased from Tom Bird. The rock is on exhibition at Bruschi's store. This find indicates that a pocket similar to the one taken from the Black Bart will soon be struck. The Tyro mine which is owned and managed by Charles Sutberland, two miles from Coulterville, is running at present with a full force of men. A deep shaft has been struck on the main ledge, where they have found first-class ore in paying quantities. It is said there will soon be a large mill built at this mine. Several experts have lately examined this mine; they pronounce it one of the best mines in the State. The Sweetwater, Southern Cross, and Mountain View mines, which are situated on Flyaway, have recently been purchased by J. Donovan, of San Francisco. James Dolan is superintending the working of them. Excellent ore has been struck in the Southern Cross, but the others have too much water to be worked at present. They are said, however, to be fully as good as the Southern Cross. The mill at these mines will soon start running under the control of Mr. J. McCort.

Mono.

PROSPECTING.—*Bridgeport Chronicle Union*, April 23: Those well known mining men, Irwin and Callahan, are looking at the Patterson District mines, and will remain there a month or more, intending to give the district a thorough examination. They have an assaying plant on the way up, and propose assaying the whole district. The great depth of snow on the mountains has caused work to be suspended on most of the mines, so that during the past two months very little work was done in the district. Some of the promising mines of the district have been handed to Mr. Irwin, and it is to be hoped he will again be with us as the superintendent of a rich mine, as he is a thorough miner and one of the most popular superintendents we have had in this county, and would be a valuable man for the Patterson District. The result of the observations of these gentlemen will be patiently awaited by our people, who have great confidence in that district.

Nevada.

NORTH BANNER MINE.—*Grass Valley Union*, April 24: The north drift on the 400 level of the North Banner mine is now in a splendid body of ore, the quartz formation being fully five feet in width, and all of it good milling rock, and several feet of it of high grade, much of which yields at the rate of \$50 a ton in free gold, independent of sulphurets and galena, which are also rich. The quartz carries plenty of sulphurets and galena, and its general appearance is that of first-class ore. The ore body is widening as the drift is extended, and there is every probability that the hacks will prove extensive and rich. A crosscut is also being made into the hanging wall of the ledge from the 400 foot station, the indications being that another vein will be cut within a short distance.

The No. 2 and 3 stopes are also yielding good ore, and the mine is producing sufficient to reduce all the ore that can be taken out, and it is expected that it will be necessary to add two more batteries to the mill during the present year. The present mill is new, having been completed last year, and is fitted up with all the latest improvements. The force em-

ployed about the mill and mine is from 35 to 40 men. Last year the mine cleared \$24,000 above all expenses, and the returns up to this date of the present year have been at the rate of more than twice that amount. For this year two dividends have already been paid amounting to \$10,000, while at the same time a reserve fund has been accumulating. The mine gives every indication of being able to continue the payment of regular dividends, and may well be regarded as one of the coming great mines of the county.

IDAHO.—The total amount of dividends paid by the Idaho Mining Co. of Grass Valley is \$5,300,650. ST. JOHN.—There seems to be nothing definite as to the erection of a mill on the St. John mine, as the management is more disposed to do underground work for some time longer before going to that expense. The shaft is soon to be sunk for another level. The present one is at the depth of 150 feet.

COE.—The developments in the Coe mine are reported to be very encouraging, and there is no doubt that the company now engaged in working the mine will put a mill up the present season. It will probably be one of 20 stamps.

Placer.

MOORE MINE.—*Placer Herald*, April 25: Thorpe and the White boys, owners of the famous Moore mine, are raising their dump platforms for the purpose of giving them more dump room, and are making other improvements preparatory to entering on a vigorous summer's work.

Shaasta.

GOLD.—*Redding Free Press*, April 25: The Bell Bros. mine at Sunny Hill is developing some exceedingly rich rock. It assays as high as \$2000 per ton. This ore is shipped as fast as it can be gotten out, and the returns are always satisfactory.

Trinity.

CHANGE IN OWNERSHIP.—*Journal*, April 25: M. C. Parlin and D. C. Dedrick have sold to S. L. Blake their one-half interest in the Chloride mine and several other locations together with mill, etc., for \$10,000. The property is looking very well and the rock is high grade. This is one of the best mines on Canon creek, but there are others equally as good and the amount of haulion that will come out of that camp this summer will surprise some of the old settlers of that section. Since the above was in type Dr. Blake has sold and deeded to C. W. Smith a one-fourth interest in the above-mentioned property.

IT LOOKS WELL.—On our visit to Canon creek this week we took a look at the new strike recently made on the Bailey mine. The ledge is small but very rich and will probably improve as it is developed. At present it is only cut in a few places on the surface but the character of the ore is the same as all the rich ore of the camp.

NEVADA

Washoe District.

CON. CAL. & VA. MINE.—*Virginia Chronicle*, April 25: 1100 level: All work has been confined to retimbering and repairing the south drift, and have started cutting out for a blower station 300 feet south of shaft. 1300 level: The upraise from the east crosscut from the south drift has been carried up 15 feet, total height, 30 feet. From this point are extracting some milling ore. The north drift from the east crosscut from the shaft station has been extended 30 feet; total length, 115 feet, continuing in porphyry, clay and quartz, all showing some value. 1500: The width and quality of the ore which is exposed in the opening 43 feet above the sill floor of this level continues to hold good, and we continue to find this ore body extending to the northeast, and the ore there continues to be of fair quality. We are continuing to stoop out ore of good quality at the end of the crosscut run west from the north drift on the sill floor of this level. 1600: Have continued to extract some ore along and above the line of the drift run east through the old stopes on the sill floor of this level; also from the stopes which are being worked both north and south from that drift. Have continued to stoop out ore of good quality at the point which is 200 feet south from the north line of the mine, and 44 feet above the sill floor of this level. From the main drift running south from the north boundary line of the mine, at a point 220 feet south from that line, the east crosscut has been extended 13 feet; total length, 54 feet; the sill floor of this level penetrating the old stopes through the old timbers. 1650 level: The usual quantity of ore has been extracted from the various openings of this level, and we are continuing to extract ore of good quality in working out from the winze No. 2, at a point 35 feet above the sill floor of the 1750 foot level. Winze No. 3 has been sunk 7 feet; total depth, 80 feet; passing through quartz of low value. From the end of the southwest drift the upraise has been carried up 15 feet; total length, 37 feet, and is now in ore of milling value. 1750 level: The crosscut run west from the drift run southwest from the northwest drift from the main west drift from the C. & C. shaft has been extended 8 feet; total length, 60 feet, continuing in quartz of some value. The drift running southwest from the northwest drift from the main west drift from the C. & C. shaft has been extended in a southwest course 12 feet; total length, 591 feet, continuing in quartz of some value. There has been extracted from all parts of the mine during the week 1,469,940-2000 tons of ore, which was shipped to the Eureka mill. The average assay value of all of the ore worked at that mill during the week (1560 tons) was \$33 per ton. Bullion now on hand in our assay office, assay value, about \$52,000. Bullion shipped to Carson Mint, assay value, \$31,338 29.

OPHR.—From the upraise started in the drift run south from the drift run west from the winze, 122 feet below the sill floor of the 1300 level, at a point 23 feet up, have continued to extract some ore which is stored in the mine of an average assay value of \$22 75 per ton.

MEXICAN.—On the 1645 level the east crosscut, No. 1, started from the main north lateral drift at a point opposite the west crosscut, No. 1, has been extended 40 feet; total length, 791 feet; continuing in a soft porphyry formation carrying fine lines of quartz, the latter showing assay value.

UNION CON.—East crosscut No. 2 on the 1465 level, started from the north lateral drift at a point 200 feet north from the south boundary line of the

A RICH find has been made a mile north of Spring City, Nev. This is a lode that parties have been trying to find for quite a number of years, as rich float has been found on several occasions upon the hillside by different parties. *The Silver State* is of the opinion that this find will be apt to create another boom for Spring City, and will be an encouragement for the new company that has but recently come into possession of the Paradise mines to push their reduction works to completion.

MECHANICAL PROGRESS

Blacksmithing in 1747.

We reproduce below from *Blacksmith and Wheelwright*, as a curiosity, the essential portion of an article on blacksmiths, which appeared in a small book published in London in 1747. It will be observed that the blacksmiths of those days were expected to make almost every article of iron work in general use. Any such thing as what we now call a "machine shop" or a "tool factory" was unknown in those days. The blacksmith did it all.

Blacksmiths.

By this Term it may be understood in general all such work or forge iron in any manner whatsoever. But in particular it signifies one who makes the Iron-work used in and about Buildings, Kitchen-furniture, &c., though it now is almost an Affront to call any one a Blacksmith, the Word Smith being used alone; or, for the sake of Distinction, with the Name of the Branch he mostly works in prefixed to it. The first which, in Order of Alphabet, occurs to me, is the Anchor-smith, whose business is to make the Iron-part (for the Stock, or Guide, is generally of Wood) of Anchors of all sizes, which differ so much as from a Quarter of Hundred Weight to a Ton or more, according to the Burden of the Ship or Craft.

It is a very useful, extensive, and considerable Part of Smithery, at which the Masters get Wealth; but then it takes up a good deal of money (500 l. at least) to build a Forge, find materials, stock it with iron, and pay many Hands Weekly.

It is laborious Work, being little else but blowing and tending a vast Fire, and striking with large Sledge-hammers, though in doing this they have a Slight and a clever Knack of following one another's Strokes, in such a manner that they seem to keep time, the Noise of which, at some distance, sounds as if they were heating Changes, there being often six, eight or ten of them striking at one Anchor.

They take Apprentices sometimes with Money, and sometimes without. Their Hours of working are somewhat uncertain; for, when they once light their Fire, which is expensive, the must finish what they began.

Anvil-maker, or Smith, is he who forges, files, and planishes the faces of all sorts of Anvils, Hammers, &c., for their Brother-Smiths, and other Handicrafts who use them, and these are all such almost who work in any sort of Metal. It is not quite so heavy a Labor as that just mentioned; though some Anvils are very weighty.

File-Maker's Business is to shape, temper and cut all sorts of Files; a very necessary Tool, and in continual Use with almost all Artificers, but chiefly those who work on Metals. This is much lighter Work than the other two.

Jack-smith, which, and making Steeple or Tower-clocks, generally make one Branch, and requires, besides Labour, which is middling, some Art, Invention, and Knowledge in Figures and Lines; and many, who have exercised this Part of the Trade, with some Reading and Application, have become great proficient in the Mathematics as well as Mechanics.

The Tire-smith makes all sorts of Iron-work for Coaches, Waggon, Carriage, and all other kinds of Carriages whatsoever; very rarely making any thing else; and it is pretty hard work.

The next, and last, that presents itself at present, is the Ship-Tire-smith, who makes all the Iron-work belonging to Shipping and Craft (except Anchors), and sometimes them likewise, especially the smaller Sorts, the Articles of which are very numerous and the Work hard enough.

They take, in common, from 5 to 20 l. by chance upon an Apprentice; their Honor of working are from five to eight and their wages, in general, 8s. a Week, and small Beer, though some clever Artificers in the noiser Branches get more.

A little money will set up a common-working Smith; but if he intends to keep a Stock of any Kind, his Cash must be increased in Proportion.

It is to be observed, that most of the above articles go into the Ironmongers Hands for Sale; as Anvils, Files, Locks, Screws, Shovels, &c., for which Reason the Makers seldom keep Stocks by them, but dispose of them as soon as made, whether bespoke or otherwise.

They were incorporated into a Company, by the Title of Blacksmiths, in the year 1571, in the Reign of Queen Elizabeth, and confirmed by King James I. Livery-fine 3 l.

Their Hall is on Lambeth-hill, in Thames-street; and their Court-day on the first Thursday of the month.

They have also a Stand in Cheap-side, in which they fit to attend the Lord-Mayor on the Day of his Installation.

Arms. Sable a Chevron between three Hammers Argent, handled and crowned Or.

Motto: By Hammer and Hand, All Art doth stand.

COPYING MECHANICAL DESIGNS.—A contemporary asks to what extent may mechanical designs be copied? In answer to its own question it says: From a legal standpoint the answer would be: Only up to the point of infringement. But in the current practice in the machinery trades, unless the design be wholly

novel, little, if any, objection is made to infringement in the line of improvement. Hammers, saws, chisels, files and the like are constantly undergoing changes in design; he whose design is improved upon, borrowing the improvement, adding something to it, and selling it as his own; another taking it from him by similar means, and so on. A large manufacturer of machinery said to the writer recently: "It doesn't pay to bring suits where the interference is very clear. Saws and planers and drills and the like have been made time out of mind, their principles having been utilized in a thousand and one ways. Even where one of our draughtsmen leaves us and goes to a rival house, carrying many of our ideas with him to be worked out with close resemblance to our own designs, it scarcely pays to fight. We take the result and make as much improvement as we are enabled to and let it go at that. The machinery trade generally is doing the same, the result being as usual—the man with the longest pole gets the most persimmons."

IRON THE CIVILIZING METAL.—An International Iron Congress recently met in New York. Among its members were not only skilled manufacturers, but men of high attainments in science. They come from almost every civilized country in the world. It is presumed that each brings with him some knowledge that is unknown to the others. Iron has been wrought since the days of Tubal Cain, but there are still many things to be found out about it. Indeed, there are good reasons for believing that many processes employed by the Saracens and others are now numbered among the "lost arts." No one can now produce steel equal to that in the Damascus sword blade. But the present age has witnessed wonderful changes in the manufacture of iron and steel. The hot-blast reducing furnace and the Bessemer converter are among the greatest inventions of all times and countries. They have rendered the production of iron and steel speedy and cheap. Other discoveries and inventions are needed to render these substances still more useful to the world. Iron is fast superseding wood in the construction of vessels and bridges. Wire has taken the place of boards and nails in the building of farm fences. Iron posts are fast coming into general use. More buildings, chiefly composed of iron, are being erected every year. The cheaper iron and steel become the greater the number of purposes to which they will be put. The civilization of a country can be accurately estimated by the amount of iron it uses. Barbaric peoples often use much silver and gold, but they make little or no use of iron. What are known as the precious metals are employed in the fine arts, but iron is the metal wanted in heavy arts. It is capable of many properties, some of which fit it to almost any use. No country has as much iron ore, coal and wood for producing charcoal as the United States, and it seems somewhat strange that, in face of the facts, the pretense can be maintained that we can not produce iron and steel as cheap here as they are produced elsewhere. It is certain that we can, though interested manufacturers are constantly trying to convince legislators that we can not.—*Southern Progress.*

A NOVELTY IN PROPELLER SCREWS.—A recent Baltimore dispatch says: Shipbuilders and marine men will this week be permitted to inspect the strange-looking new steamer Howard Casard, which Mr. Myer, the inventor, asserts will revolutionize ocean travel. The shaft and propeller will be adjusted, giving the maritime people an opportunity to see in place a four-bladed screw, each blade of which is set on a different line of rotation, or in spiral order, increasing in pitch toward the stern, as compared with preceding blade or blades. The object is to embody in a single screw as much surface as now exists in a twin-screw driven by the same amount of power. The inventor asserts that this feature of the vessel is an experiment. The Casard will soon receive the finishing touches to make her ready for the dock trial, which will take place about April 15th.

LARGEST FORGING PRESS IN THE WORLD.—The first large forging press that ever was made is now in full work at the armor plate factory, in Sheffield, of John Brown & Co., Limited. It is of 4090 tons, and is worked by 2000 horse power pumping engines, and commanded by power traveling cranes, capable of lifting 150 tons. At the works of Mr. Krupp, and at those of Messrs. Schneider & Co., in France, similar processes are now at work, and one has been erected at the Terni Works, in Italy, where the forging of guns and armor plates is largely carried on. A 4000-ton press, ordered by a Chailion company, has been delivered, and is now in course of erection.—*The Mechanical World.*

ANCIENT AND MODERN PRACTICE IN PUMPING machinery is very well exemplified at the Jersey City pumping station. There are in one house two immense, by contrast, pumping engines of the old English type—weighted plungers and a wilderness of rods and levers and clap-traps about the engines—while in another and more modest building are two compound direct-acting pumping engines, occupying but a small part of the space, but, as one of the engineers remarked, "beating the big engines out of sight." The day of these old ponderous pumping machines has gone by, but they were excellent in their day, the better types of the present day only denoting the progress that is to be expected.

SCIENTIFIC PROGRESS.

The Causes of Rust.

An Eminent Professor Shows That it is a Rather Curious Combination That Causes Iron to Rust.

At the regular monthly meeting of the Leeds Association of Engineers, held in the Chemical Lecture Theater of the Yorkshire College, England, Prof. Smithells, of the college, delivered an interesting address, for extracts from which we are indebted to *The Ironmonger*.

He remarked that if they were to do anything on the subject of rust, they must begin by studying the conditions under which rust was formed, getting to know as much as possible about the phenomenon itself. The question was, was it the chemist or engineer that was to tackle the problem. The answer in this case, as in so many others was, that the two must go together; they must combine theory and practice. His object would be mainly to take the chemist's attitude, and to explain to them the chemistry of rust, and to hint at one or two ways in which attempts have been made to obviate its formation. Rust, of course, was more or less a general phenomenon. It was not restricted to iron, but was most noticeable in the case of iron because iron was the most abundantly used metal, because the rust of iron formed rapidly, because it assumed a scaly character, because of its colors, and because of the fact that rust was a thing that appeared to grow in the case of iron, but it did not grow so rapidly, if at all, in the case of other metals. Other metals, of course, did rust.

They knew they could not expose the bright surface of copper or zinc without the surface becoming dim. These metals might, therefore, be said to rust in their respective ways, but the rusting was very slight as compared with iron, which was the most susceptible to rust. Iron rust was found to consist of three elements—iron, oxygen, and hydrogen. That rust did contain water could be shown by the simplest experiments. That rust were oxides they could easily prove, because they could produce rust by burning metals in oxygen alone, hence there could be no other element present, but the way that might appeal to them would be by getting the metal back again from the rust, and the oxygen as well. The lecturer demonstrated this by experiments with the rust of quicksilver, and also with iron rust. The experiment he had done he remarked was a very suggestive one; because in getting the iron back from the rust in that particular operation he had done what had to be done so often in the process of soldering. They knew that before they could unite two pieces of metal by solder they must use a flux. The reason was that the two metals might be covered with a thin film of rust, and the solder would not adhere to these two nuclear surfaces.

What was the cause of iron rust? They all knew that rusting was favored by the presence of the air, and by the presence of moisture, but they wanted to know which of these two was the real cause, whether both were necessary, and whether anything else took part in the process. They wanted to know why rusting went on so rapidly and at different points, and how it was effected by the different compositions and the qualities of the metal, and by impurities in the metal, in the air, or in the water. Professor Smithells then showed some specimens of iron in jars, which he had been preparing for some time. One was a piece of iron in dry oxygen, and he explained that that would not cause the iron to rust. Next he showed a piece of iron which had been sealed up in water for some days, remarking that it was found that when they excluded air and other gases from the water no action took place, and a second conclusion was that water alone would not affect iron.

The next question was, would air and water together affect iron? That experiment had been done, and it had been shown that wherever action had taken place at all, the action had been exceedingly insignificant, and the question arose, what was it that was absent and that caused the rust? The one ingredient which was present in one of the jars, and was not present in the cases he had shown, was carbonic acid gas. Carbonic acid gas existed in the atmosphere to a small extent, and it was this gas in the air that was all-important in the operation of rusting. Pure air, pure water, pure carbonic acid would not act singly upon iron; pure water and pure air would not act together upon iron; carbonic acid and air would not act together upon iron, but when they had carbonic acid water, and air together, they got symptoms of rust. It was carbonic acid that really set rust on, and when it was found the carbonic acid was liberated and attacked the layer beneath. That was why rust has got the property of traveling inward.

How could they prevent this action of rusting? There were many things which had been tried. They might paint the iron, and if they observed certain precautions they might have an effective method. One precaution was that the metal must be perfectly clean. A spot of rust embedded below a coat of paint would often break out of itself. Then there was the method of covering the iron with oils and tarry matters. There was also the process of galvanizing iron; the process of enameling, which was very useful for small articles, but the enamel was apt to chip off; and there was the Bower-Barff process, which was worked at

Keighley, and which was an admirable process. Alluding to boilers, he said, by putting soda into them, not only did they correct acidity of the water, but they introduced something which would absorb the carbonic acid gas, and prevent it acting in a rusting capacity.

WHAT KEEPS THE BICYCLER UPRIGHT?—Let us suppose a cyclist mounted on his wheel and riding, say toward the north. He finds himself beginning to tilt toward his right. He is now going not only north with the machine, but east also. He turns the wheel eastward. The point of support must of necessity travel in the plane of the wheel; hence it at once begins to go eastward, and, as it moves much faster than the rider tilts, it quickly gets under him, and the machine is again upright. To one standing at a distance, in front or rear, the bottom of the wheel will be seen to move to the right and left, just as I moved the foot of the skeleton frame a moment ago. I conclude, then, that the stability of the bicycle is due to turning the wheel to the right or left, whichever way the leaning is, and thus keeping the point of support under the rider, just as a boy keeps upright on his finger a broomstick standing on its smallest end.—*Popular Science Monthly.*

[What keeps a hoop in an upright position when thrown off to trundle by itself? Does it keep its position by turning to the right or left—or by its centrifugal action? What is the difference between a bicycle wheel and a hoop in motion?—EDS. PRESS.]

THE RAPIDITY OF THOUGHT.—Much speculation has been set on foot in regard to the rapidity of thought; but Prof. Donders of Utrecht has recently made some interesting experiments in this direction by means of two instruments, which he calls respectively the "tachograph" and the "nerveometer." His experiments thus far show that it takes the brain one sixty-seven hundredths of a second to elaborate a single idea. He says: "Doubtless the time required for the brain to act is not the same in all individuals. I believe, however, that these instruments may be so far perfected that we shall be able to determine the mental caliber of our friends without our friends knowing that we are testing their aptness." And again: "For an eye to receive an impression requires seventy-seven hundredths of a second, and for the ear to appreciate a sound, one hundred and forty-nine hundredths of a second is all that is necessary, which, however, acts with nearly double the rapidity of the eye."

THE SOURING OF MILK IN THUNDER STORMS has just received a scientific explanation at the hands of an Italian savant, Prof. Tolomei. He has found that the passage of an electric current directly through milk, so far from souring it, actually keeps it sweet, so that it does not turn until the sixth day; when, however, an electric current is passed over the surface of milk it soon becomes sour, and this the professor attributes to the generation of ozone, since the souring is more rapid when the current passes silently than when it is discharged explosively, more ozone being generated by the former than by the latter method. The fact that the souring of milk can be retarded by so simple a procedure as the passage of an electric current may prove of practical value, and offer a safer way of preserving milk than by the use of antiseptics.

SHOULD THE GREGORIAN CALENDAR BE SUPERSEDED?—A correspondent of the *Scientific American* says: The Gregorian calendar, as it is, loses one day in 3600 years. The rule for leap year is, add one day to February every four years, unless it be divisible by 400. It would be much better to add one day to February every five years, two days every 25 years, and three days every 450 years. Thus every fifth year, February would have 29 days, and the year 366 days; every 25th year, February would have 30 days, and the year 367 days; every 450th year, February would have 31 days, and the year 368 days. By this plan, every year ending in 0 or 5 is a leap year, and could be known at a glance. The error in this amounts to one day in 50,000 years.

SINGULAR.—A gentleman put on a pair of woolen stockings over his silk ones on a cold winter day. At night, he pulled the stockings off without separating them, and was astonished by the crackling noise and even the sparks of electricity which followed. When he drew the silk stockings out of the woolen ones, the electrical attraction was so manifest that the stockings would incline toward one another, when held some distance apart. It happened that the silk stockings were black and the woolen ones of light color; but when he tried the experiment with both stockings of the same color, there was no electrical manifestation. Why?

HOW THE DIAMOND OCCURS.—Geologists have proved that the diamond mines of South Africa are situated in vents or chimneys, varying from about 70 feet to 1500 feet in diameter, and descending vertically through the schists, which form the ordinary strata of the district. These vents are filled up with fragments of silicified and magnesian rock, in which the diamonds are scattered, and before the digging began, each was capped by a hillock or "kopje." They are 17 in number, and run in a straight line about 120 miles.

GOOD HEALTH.

Remedy for Blood Poisoning.

It is claimed that Mr. Ernest Tanner of Baltimore, Md., a gentleman without affix of "M. D." to his name, has compounded a remedy to counteract the ill effects from the bite of rabid animals, reptiles, insects, etc., all of which exist in such numbers that members of the human family are constantly exposed. The remedy is a vegetable compound embodying rh grass, plantain and hazel, all easily obtainable and manufactured by a simple and inexpensive formula. This medicine is taken internally, and also applied externally to the bite. A good, reliable remedy should be in every household, as poisonous insects are liberally applied to nearly all communities, and in localities abounding in venomous snakes, no one should be without a ready antidote.

It is claimed that this remedy only requires a little systematic effort and energy to develop into a profitable and beneficial article of large demand. If the gentlemen of the medical profession would only throw aside their professional exclusiveness, now and then, and devote a little attention to such announcements as the above, they would add, much more frequently than they now do, to their catalogue of remedies.

The history of medicine shows us that the unprofessionals have, by either accident or study, added quite as much, if not more, to medical progress within the last three centuries, than the profession itself has done. An important factor in regard to these unprofessional discoveries is the fact that they have in nearly, if not every instance, been derived from the vegetable kingdom, while the chief study of the regulars has been almost exclusively confined to the mineral kingdom.

The tendency of the day is to substitute vegetable for mineral derivatives in the practice of medicine, and there is good reason to believe that the day is not far distant when the shelves of our druggists will be almost completely relieved of the dangerous and poisonous nostrums which owe their origin chiefly to the mineral resources of the chemist. Nature seems to have provided in the vegetable kingdom remedies for almost or quite every ailment. We have evidence of this in the animal kingdom. Nature seems to have given an almost universal instinct to animals to search out and feed upon certain herbage, which will remove almost or quite all the ailments which come to them in a state of nature. There are, however, ailments which afflict them when under restraint or an abnormal mode of life, that they do not seem to know what to do for. Man, in such cases, generally intervenes with his mineral preparations. The now well-known cancer remedy, which is meeting with such remarkable success in this city, is composed exclusively of vegetable compounds and applications of a non-caustic nature, helped out only with new sweet cream or butter direct from the churn—the smallest possible remove from the vegetable kingdom. This may be regarded as a most successful application of vegetable remedies to one of the most persistent and malignant ailments with which humanity has ever been afflicted. The malignant nature of this ailment is especially manifested when treated with the knife or the poisonous mineral application, so universally, yet so unsuccessfully, employed by the medical faculty at large.

THE ELECTRIC LIGHT IMPROVES THE APPETITE AND STIMULATES SLEEP.—It has been remarked as snowing what a powerful element of health the electric light is, that the general health of those who use it improves, their appetite and their ability to sleep increase, and the visits of the doctor become less frequent. This is especially apparent in the statistics of the attendance of working people in factories and other places. In the savings bank in Queen Victoria street, London, where 1200 persons are employed, the absences from illness have been so far reduced that the extra labor gained is said to have paid for the electric light. The influence of artificial light on the eyes has also a very important sanitary bearing. It has been asserted that the injury to the eyes, of which the growing short-sightedness of the day is but one result, is due to the heat rays and not to the light rays. If that be so, the electric light is less injurious than any other. If the eyes are exposed to the strong light of the arc lamp, its ultra-violet rays have a painful effect, but no one has ever complained of the influence of a steady glow lamp upon the sight, and it is possible to read and write for many hours by such a light without experiencing the least fatigue.—*New York Sun.*

A CURE FOR DIPHTHERIA.—The following remedy was discovered in Germany, and is said to be the best known. At the first indication of diphtheria in the throat of a child, make the room close; then take a tin cup and pour into it a quantity of tar and turpentine, equal parts. Then hold the cup over a fire so as to fill the room with fumes. The little patient on inhaling the fumes will cough up and spit out all the membranous matter, and the diphtheria will pass off. The fumes of the tar and turpentine loosen the matter in the throat, thus affording the relief that has baffled the skill of physicians.—*Hall's Journal of Health.*

PREVENTION OF MERCURIAL POISONING.—Jules Mayer, an employee in a French mirror factory,

has lately ascertained that by scattering through the working rooms a pint or a half-pint of aqua ammoniac every evening, all danger from the absorption of mercurial vapors will be in a measure prevented. This practice has now been in use for several years in his establishment without the occurrence of any new attack of mercurial poisoning.

USEFUL INFORMATION.

THE SMOKE NOISE IN CHICAGO.—The report of Smoke Inspector Young, of this city, published in the *Tribune* of Saturday, gives reason to hope that ere long the dreadful smoke nuisance will be reduced to an endurable state. The railroad-locomotive part of the problem has long been recognized as the most difficult to deal with, but it now appears that the railroad officials see that it can be abated, and many of them are working to that end. Some of the roads have abated the nuisance on all their locomotives which run within the city limits, and some of the rest are making the required changes as fast as they deem practicable. The others report little progress, which may be accepted to mean that they have not entered into the spirit of the proposed reform, and need to be spurred up to a performance of their duty to the community. The Smoke Bureau has decided that sufficient time has been given for compliance with the anti-smoke ordinances and that a vigorous prosecution will be instituted against the dilatory ones to see what effect fines will have. This should not have been promised, like so many others that have been made, but should be carried out faithfully. The Smoke Bureau reports that much has also been accomplished in abating the smoke nuisance in factories, hotels, and office buildings, and the clearer skies with which we have been favored in the last few weeks show that this is not merely an idle boast. But there is a vast deal yet to be done before the course is removed and the air rendered clean.—*Chicago Tribune.*

[Why cannot some steps be taken in the same direction in San Francisco. Such action is beginning to be greatly needed. EDS. PRESS.]

THE GREATEST IRON PORT IN THE WORLD.—Escanaba is the county seat of Delta County, Michigan. It lies at the foot of the great pine forests, and overlooks Little Bay de Noquet, the headwaters of Green Bay. Five years since it was practically a village in the wilderness. To-day finds it a city with a population of 8,000, lighted by electricity, having a well equipped fire brigade, waterworks with a capacity of 4,000,000 gallons per day, a high school and three other schools, six churches, three newspapers, a railway station where 216 trains arrive and depart daily, and it will shortly have an electric street railway in full work. Its annual retail trade is estimated at \$3,000,000, and its wholesale trade, including iron ore, pig iron, lumber, and coal, at about \$25,000,000. According to Mr. Nurey's carefully written report, capable of the fullest verification, Escanaba is the greatest iron port of the world. He tells us that during the navigation season of 1890 it shipped 3,700,000 tons of iron ore, or nearly double that of all the ore ports of Michigan, Wisconsin, and Minnesota combined. Its lumber output amounted to about 120,000,000 feet, while the freight capacity of the vessels entering and clearing from its port exceeded 8,000,000 tons. This compares with the tonnage of the greatest seaports of the world, which are: (1) London, 19,000,000; (2) Liverpool, 14,000,000; (3) New York, 11,000,000; and next comes Escanaba with 8,000,000 tons.

UNINFLAMMABLE WOOD.—Wood cannot be rendered incombustible, or, more strictly speaking, non-alterable by heat, but its non-inflammability may, to a considerable extent, be insured so as to preserve buildings from a limited and temporary fire, at any rate until assistance arrives. It is, however, hopeless to expect a building encumbered with inflammable substances to pass through such a test uninjured. The methods of preserving wood against fire are of two kinds—the injections of saline solutions and the application of a paint or coating. The former appears but little practical; and, indeed, short of proof to the contrary, it must be considered dangerous in the case of wood of large dimensions. This system is, however applicable to small pieces of wood. Of all the substances recommended, a concentrated solution of phosphate of ammonia is undoubtedly the best, the use of this substance, notwithstanding its high price, possessing such great advantages that it should be employed in all cases where expense is no object. In the majority of cases, however, coating with a brass is the only practical solution of the question, and Professors Bondin and Denny, of Ghent, recommend as the substance most suitable for use in this manner cyanide of potassium and asbestos paint.

THE PARTITIONMENT OF AFRICA.—Only 2,500,000 of the 11,000,000 square miles of Africa remain in the hands of native rulers. France has 2,300,247 square miles, England 1,900,445, Germany 1,035,720, Congo Free State 1,000,000, Portugal 774,993, Italy 360,000, Spain 210,000. While the share of France is largest, England's is most valuable.

TO SOLVE THE CHEAP FUEL PROBLEM.—Among the latest attempted solutions of the cheap fuel problem is the method of a German inventor, who proposes to manufacture gas by

dropping a stream of crude petroleum through a blast of cold air from a force pump. The gas thus obtained will be confined in a regular cylinder open at one end, where it will be lighted. This produces an intensely hot flame of several feet in length. By means of this flame the inventor proposes to heat boilers, and he maintains that the heating of large blocks can thus be reduced very considerably.—*Com. Ad.*

STEAM BOILER NOTES.

NOTES ON STEAM FITTINGS.—The nozzles of a large steam drum, that is, those forming the connection between the drum and the boilers are very seldom put on as they should be. For drums, up to ten inches in diameter, which are made usually of ordinary steam pipe, the connections from the boiler are generally made by means of an ordinary screwed tee. The pipes leading from the drum to the engine and other parts of the works are usually the full size of the drum. Often they are not over six inches in diameter and are taken out by means of the usual form of fittings. As the pipes are led horizontally from the drum with all centers at the same height a chance is left for water to collect in the lower part of the drum, which is liable to cause trouble unless a drip is attached. This drip must be connected to all the boilers and supplied with valves so that the water may be returned to any boiler of the battery that may be running alone. There is no particular harm in this arrangement except that it is in the nature of a makeshift. The best way of making nozzle attachments to drums of large size either riveted or made up of welded pipe when the branch pipe is taken out on the center, is to have the cast iron screwed nozzle riveted to the inside, which allows the rivets to be driven from the outside. The iron of the drum is brought closely down to the flange of the nozzle and the canking edge is outside, thus allowing of a good job at low cost. Besides main steam pipe connections it is advantageous to use eccentric fittings as couplings for long lines of pipe and especially on pipes used in steam heating systems. With the ordinary style of couplings, when the size of a steam main is reduced, it is necessary to put in a drip pipe which sometimes involves considerable expense, where if eccentric reducing couplings (which cost no more than the others), were used, the condensed water would flow on freely.—*Exchange.*

BACONING OR BULGINO OF BOILER PLATES over the fire is in nearly every case traced to the use of oil in the boiler. Oil is sometimes inadvertently fed to boilers by false economy of turning the exhaust steam into the water tank, where the engine oil is caught and pumped into the boiler. Oil gathers the soot and dirt into a cake, which may settle on the fire sheet and thus prevent contact with the water. The intense fire heats the iron red hot and the pressure bulges the plate. Scale, if allowed to accumulate in large quantities, may possibly also cause bulging, but we have yet to see the first case in a cylinder boiler that was not traced to oil.

A POINT REGARDING FEED WATERS FOR STEAM BOILERS.—Mr. Leo. Vigon's new method of analysis applicable to industrial waters which have to undergo a chemical purification leads him to the conclusion, according to *Moniteur Scientifique*, that in order to determine the elements of chemical purification, or the anti-incrustation agents, it is sufficient to determine the free or the half combined carbonic acid, and to determine the quantity of sodium carbonate necessary to convert the soluble salts of calcium and magnesium into carbonates which are chemically neutral.

WATER CONSUMPTION.—The actual water consumption of an engine is always larger than that shown by the indicator. The amount of this unindicated loss is very nearly the same in an engine under different loads. At 40 pounds mean effective pressure it is a safe rule to assume an unindicated loss of 25 per cent. The percentage of loss will therefore be greatest under light loads.

A SAFETY-VALVE, in order to be, in reality, what its name implies, should be so proportioned, fitted up and piped, as to insure the boiler to which it is attached against an over-pressure of steam, when all other outlets are closed and a brisk fire in the furnace. How many engineers who read this have ever tested their safety-valves in this way?

AN ENGINEER is very liable to grow careless of the dangers about him as he becomes familiar with his work. If care is ever necessary in dealing with machinery it is always necessary, and it often proves disastrous that familiarity with danger brings contempt as well as in other cases to which this saying applies.

A HIGH-PRESSURE ENGINE runs by the direct pressure of the steam only. In a low-pressure engine the steam is condensed with water or otherwise, and a vacuum formed in front of the piston, adding from thirteen to fourteen pounds per square inch to the power of the piston.

SATURATED STEAM at 60 pounds pressure to the square inch has a temperature of 292.52°F., and one pound of the vapor occupies a volume of 7.0328 cubic feet, and one cubic foot weighs 0.14219.

SHOP NOTES.

NOTES ON BELTING.—A prominent belt maker says all ordinary pulleys up to twelve inches broad should have a round or corve of not less than one-eighth of an inch; others, ranging up to twenty-four inches broad, should have a curve of not less than five thirty seconds of an inch; while the curve for such as are over twenty-four inches broad should not be less than one-fourth inch. For pulleys twelve inches in diameter and under, running at very high speeds, the corve ought not to be less than double the foregoing.

It does not take half the power to make a quarter turn with belts that most millmen imagine, if a belt long enough is used, and pulleys for guides the same as for shaft wheels. Place the shaft wheels overhead as close together as possible, and let the belt hang straight down from both sides of both wheels to the floor. It will take three wheels, six hangers and three shafts to complete the system, to say nothing about a half-dozen rollers, but it will take care of itself for years, and no one will ever know that an angle turn was ever made in the mill except for the space that it occupies.

As showing the effect of elasticity of belts, it is a fact that owing to the slip, elasticity and thickness of a belt the circumference of the driven pulley does not run as fast as the circumference of the driver, and taking two pulleys of the same diameter, one can be made to run twice as fast as the other without slipping by using an elastic rubber belt.

TO REMEDY SWAYING AND OSCILLATION.—Frequently the oscillations of the main belt in a mill come in unison with the heat of the engine, and a pretty perceptible slapping about of the belt is noticeable. The heat of an engine will often come in sympathy with the rhythmic sway of the building, and so increase it as to be very perceptible. If this were continually going on in exact time it would become so great in time as to be dangerous; but one or the other gets ahead and mixes the movement, so that it gradually ceases until they are again in unison. If the speed of the engine is changed in either case the swaying will be kept mixed all the time instead of occasionally. On long lines of shafting this will appear also, the pull on the belt at the commencement of the stroke being in unison with the spring of the shaft, thus causing a marked oscillation. The same remedy is applied here, to mix the two movements purposely, and the trouble is partly removed, if not entirely.

COMBINATION TOOLS.—Every man who has done outside work, knows how troublesome the augers and long bits become when packed with their handles in a tool-chest or box. This trouble may be overcome by fitting all the augers to one handle, and all the bits to one brace; then make two chucks, one to fit the brace, the other to fit the auger handle. Make all the augers to fit the brace chuck, or rather the chuck to fit all the augers, then make another chuck to fit the auger handle and all the bits. With this combination, all the bits, augers and handles are interchangeable, and never a job can be brought along but can be handled. In addition to the handles, a ratchet chuck may be made for boring in a corner, or where there is not room enough to swing brace or auger handle.

DEFICIENT WORKING OF MACHINERY.—To locate the deficient working of machinery with numerous points of friction causes often both annoyance and waste of time, owing to the surrounding noise interfering with the observation of the sound to be isolated. The *Revue Industrielle* mentions as an effective and exceedingly simple means of overcoming this difficulty the use of a rubber tube about a metre long, one end of which is placed in the ear and the other passed over the suspected spots. The vibrations from all other parts of the one covered being excluded, it is an easy matter to locate jarring noise, and when found, to observe the intensity and periodicity with which it occurs.

HOW TO FIND THE EXTENT OF A CRACK IN METAL.—A crack in a piece of metal is prevented from extending farther by the well-known means of drilling a hole where the rent ends; but when the hole is not bored on just that spot the crack is apt to continue beyond the hole. To facilitate the search for the exact point, *Revue Industrielle* recommends moistening the cracked surface with petroleum, then wipe it and then immediately rub it with chalk. The oil that has penetrated into the crack exudes and thus indicates with precision where the crack stops.

TEMPERING BRASS.—Brass which has been rendered hard by compression may be tempered the same as steel. To do this a piece of polished steel is placed on the article to be tempered, and heat is applied so as to affect the steel and brass equally, and the temper of the brass will be indicated by the color of the steel.

STEAM is a willing servant, and will turn any crank and ask no questions; but it depends upon who made the crank how long it keeps turning.

HANGERS with adjustable boxes will be found to be the most convenient for keeping the shafting in line.

Passing Events.

This has been "President's Week" in San Francisco, and the Chief Executive of the Nation has received a hearty welcome and such attentions as become his station. The city has been crowded with visitors and has been in holiday attire.

The coast defense vessel, Monterey, was launched at the Union Iron Works' shipyard this week, in the presence of the President and his party and many thousand people. The launch was, in every way, successful. Two more Government vessels are on the stocks at the works, one of them the largest ever contracted for on this coast.

The discoveries in the Deep Creek country, Utah, are still attracting great attention. The number and richness of the strikes in the camps of that district will still further draw attention to Utah's great mineral resources, and furnish a new field for mining labor.

The remarkable advance in the business of granite quarrying in California, referred to in another column, is only another proof of the variety of mineral resources of this State, only now being properly developed.

California Granite.

Our Important Quarrying Industry.

Of the various kinds of stone quarried in the United States, granite is capable of the widest application, when all the uses to which the stone is put are considered. During the past ten years a wonderful increase is shown in the development of the granite quarries of this country, owing to the demand for the stone for building and other purposes in the large cities. A very notable increase in production has raised California from the ninth place in the Tenth Census to third place in the Eleventh. Massachusetts and Maine are still the foremost granite-producing States, but to hold these positions the increase in value of output has been very great. The great increase in production in California is largely due to operations in the Folsom granite quarries, much of that stone having been used in the construction of the dam, the canal and the power-house at the prison. That work has been chiefly done by prison labor. In Sonoma county granite is extensively quarried for paving blocks. The stone is really basalt, and has given satisfaction for paving purposes. Most of the paving blocks of the State come from that county.

The following kinds of granite are being quarried in this State: Biotite granite, Placer county; hornblende-biotite granite, Placer and Sacramento counties; hornblende granite, Placer county; quartz diorite, Placer county; basalt, Solano, Sonoma and Alameda counties; andesite, Shasta county; andesite tufa, Solano county; quartz porphyry, San Bernardino county; basaltic tufa, Tehama county.

A Census Bulletin just issued by Special Agent Wm. C. Day, on "The Granite Industry of the United States," gives in a condensed form many interesting facts, but we have only space to collate what relates to California.

There are at the present time 26 granite quarries in this State, there being but three others which have a greater number—Massachusetts, Maine and New Hampshire. The locations of these quarries are as follows: Five at Agua Caliente, Sonoma county; one each at Angel's Camp, Calaveras county; Arcata, Humboldt county; Berkeley, Alameda county; Monrovia, Los Angeles county; Cordelia, Solano county; Declezeville, San Bernardino county, and Exeter, Tulare county; five at Folsom, Sacramento county; one each at Grass Valley, La Canada, Los Angeles county, and Lakeside, San Diego county; six at Lincoln, Placer county; two at Victor, San Bernardino county; one at Los Guilcos, Sonoma county; two at Nevada City; one at Novato, Marin county; two at Oakland; one at Temescal, Alameda county; one at Penn's Grove, Sonoma county; four at Penryn, Placer county; three at Petaluma; three at Raymond, Fresno county; ten at Rocklyn, Placer county; two at Loomis, Placer county; one at National City, San Diego county; two at Temecula, San Diego county; five at Sonoma; four at Santa Rosa, and one at South Gullcoos, Sonoma county.

It will thus be seen that granite is found in all parts of the State. The most extensive quarries are located in Placer county, and the granite from them is extensively used in San Francisco for building purposes.

The statistics with regard to the production of granite in California furnish many points of interest. Thus, the 76 quarries in this State produced 4,761,411 cubic feet of granite last year, the value of which was \$1,329,018. To do this work 1803 men and boys, 139 animals and engines of 1026-horse power were employed. The total expense incurred was \$973,276, of which \$809,205 was for wages, \$131,837 for supplies, and the balance for incidentals. The total amount of capital invested is \$2,829,794, which is nearly one-sixth of the total for the entire country. The earnings of the employees has a high standard in California by comparison with the other granite-producing States. Foremen average \$4.35 daily, quarrymen \$2.38, mechanics \$3.52, laborers \$2.11 and boys \$1.05. These wages are from 25 to 50 per cent higher than are paid in the principal granite States.

A remarkable fact is, that in the amount of capital invested in granite land, California is first, Maine being second, Georgia third and Massachusetts fourth. The total capital invested in the granite business in this State is \$2,829,794—largely in the value of the land.

Of the entire amount of granite quarried in

this State last year, \$419,816 worth was used for building purposes; 7,303,321 paving blocks were used—valued at \$297,236, or \$40.70 per 1000. Notwithstanding the higher wages paid here, the cost of producing these blocks was less than in any other State. Outlets of California the cost ranges from \$42.14 to \$78.67 per 1000. In Maine it is \$46.55, and in Massachusetts \$62.01.

For cemetery purposes the California quarries furnished material to the value of \$115,114. For bridge, dam and railroad work the value of the material quarried was \$237,475—this State standing easily first in this respect. In street work California is second, and in the value of the product for building purposes she is fourth. The highest figures for wages are in the Western States—\$2.11 in California and \$1.96 in Colorado.

The total number of cubic feet of granite produced in the census year in California was 4,761,411; total value of product, \$1,329,018; total wages, \$809,205; total expense, \$973,276; total capital, \$2,829,794; percentage of profit on capital, 12.57; percentage of profit on value of products, 26.77; cost of product per cubic foot, \$0.18; percentage of wages paid to total expense, 83.63; wages paid per cubic foot, \$0.15; percentage of wages to total value, 66.51; value per cubic foot, \$0.33.

There is no doubt but these statements will surprise many who did not know to what proportions the granite-quarrying business had grown in California. Great care was taken in collecting this data, most of the quarries having been personally visited by special agents. The value placed on some of the quarry land may be, and probably is high, for the reason that the area included was very large, while the value per acre may not have been excessive. California out a very small figure in this connection at the previous census, but this time she takes a stand beside States which have been granite-quarrying for a century or more.

Our Distinguished Guests.

California has done herself much credit by the cordial welcome extended to President Harrison and his party. Everywhere the most sincere enthusiasm has prevailed and exceptional marks of esteem and honor have been paid to the chief executive, in which those of every shade of political opinion and interest have eagerly participated. There have been tokens of welcome most unique in design and in spirit characteristic of the State and its citizens. The "California style" has dropped out and seems very agreeable to the recipients of our honors. No doubt the effect upon those high in the National affairs will be toward a truer appreciation of our Western spirit and the resources which we are developing, and this will be of inestimable value to us in many ways. Next week the President and his party will be in Oregon and Washington, and the northern part of the coast will continue the welcome which has been sounded on so high a key by the people of California.

President Harrison and his party have had dinners and receptions without number, but have found time to visit points of interest about the city, including the Cliff House, Park, Presidio and Fort Point.

Probably the most interesting trip for the President was that on the bay, on Tuesday. A fine steamship was provided for the President, and with him went the prominent officials of the State and city. The steamship was escorted by numerous Government vessels including the cruiser Charleston, revenue cutters Rosh and Corwin, the Hassler and the Madrona. Salutes were fired from the vessels and the forts.

A great fleet of excursion steamers, tugboats, yachts and other craft accompanied the President's vessel. The larger vessels went out through the Golden Gate, giving the President a chance to see that famous portal and its surroundings. He was enabled to examine the fortifications, and see the necessities of this post for further work in that direction. Officials with detailed knowledge of existing conditions were at his side to answer questions. After returning from outside, the fleet passed up through Raccoon straits, past the islands of the harbor, and proceeded to the Union Iron Works, where the launching of the Monterey took place, Mrs. Harrison pressing the electric button which released the vessel from the land.

The arrangements at the Union Iron Works were very perfect, and everything went off according to program. There were no accidents to mar the occasion, and the President was well pleased with the day's events.

He has since visited the Stanford University at Palo Alto, the cities of the Santa Clara valley, Monterey, Santa Cruz, etc., and visits Sacramento and Oakland on Saturday, leaving for Oregon and Washington on Sunday night.

Slag Cupolas.

Cuts on next page show the slag cupola used at the Lake Superior copper mines. The engravings first appeared in a paper by Prof. Eggleston in Copper Refining in the U. S., read before the American Institute of Mining Engineers and then in Mr. Peters' work on Modern Copper Smelting, from which we reproduce them. An elliptical furnace provided with sectional cast-iron jackets, forming a hosh 29 inches high immediately above the tuyere level, has been in use for many years for treating the slag resulting from the fusion of the Lake Superior Metallic "Mineral" in reverberatory furnaces, previous to the refining operations, which is merely a later stage of the same fusion.

The cupola referred to is a modification of McKenzies jog-iron cupola and has in place of distinct tuyere openings a five-eighths inch slot encircling the entire furnace and just below the water hosh. Below the tuyeres is a 34-inch deep crucible, nearly the full size of the furnace and closed by a drop-bottom protected by a few inches of sand. The water hosh consists of curved sections of cast iron fitted closely together and five-eighths of an inch on the inner and lower sides, while the external and superior sides have only half an inch of metal. This hosh is 22 inches high and is kept cool by a three-quarter inch supply pipe furnishing 25 gallons of water per minute.

The cupola is 7 feet 6 inches in height from tuyere level to charging door, and has a greater axis of seven feet and a smaller one of 4 feet 9 inches.

A peculiar inverted siphon arrangement for the lapping of the blast during the continuous slag flow will be noticed by reference to the illustrations. As even during the ten-hour campaigns made by these furnaces (owing to the small lots of slag belonging to separate mines) two of these slag flows are pretty thoroughly used up, they will hardly be likely to come into general use.

The material smelted is a siliceous slag from the reverberatory furnaces, carrying some 15 per cent of copper and over 40 per cent of silica. About 20 tons are smelted in ten hours, using anthracite as fuel, brief attempts to use coke having resulted in an increase in the richness of the final slag. About one pound of coal is used to smelt three pounds of slag, probably the highest consumption of fuel in the United States. Blast is furnished by a No. 5½ Baker blower, at a pressure of ten ounces per square inch. The metallic copper produced is impure, containing some five per cent of iron and half of one per cent of sulphur, the latter coming from the fuel; while the large amount of iron present is also due to the powerful reducing action of the anthracite, which seems necessary to decompose the silicate of copper present in the slag.

THE SMITH MINE.—Some weeks ago we mentioned the fact that the Smith mine of West Point, Calaveras county, had shipped some 1800 pounds of ore, which yielded from \$125 to \$141 per ton. The mine was owned by Tibbey & Porterfield, but since then Mr. Finck, of Will & Finck, has bought an interest. The shaft is down 110 feet, with the ledge widening. Two teams are hauling sulphurets to Valley Springs, from which place they are shipped to the Selby Works. The free ore is being piled up for future milling. Some fine specimens go \$200, but the run of the free-milling ore is about \$60. Three tons a day are taken out in sinking. Ten men are at work, but when the shaft is down 50 feet deeper six more men will be put on and they will begin to drift. Mr. Sales, of Mokelumne Hill, is superintendent and Robert Smith, of West Point, foreman of the mine.

A RUMOR has been published that the Anaconda copper mines, Montana, have been sold to the Rothschilds for \$25,000,000, but it is not confirmed by interested parties in this city.

New Gold-Saving Apparatus.

George H. Bagley of Astoria, Oregon, has obtained a patent through the MINING AND SCIENTIFIC PRESS Patent Agency for an improved form of gold-saving apparatus, which is illustrated herewith.

A is the pan or table of the apparatus, which may be made of any suitable material, preferably of rubber, and provided with an inclosing flange, a. The table is made concave in the direction of its width, so that its middle throughout its entire length is lower than its sides; the table to be secured to a bottom framework. The table is suspended from arms, B, so that it may have a swinging, lateral movement, a jar being imparted, by means of the buffers, b. Motion may be imparted to the machine by any power desired. The surface of the table is dotted with numerous agitating pins, inclining with the flow of the material.

E is a cross riffle, the lower side conforming to the concavity of the table, and secured in a manner so as to be easily moved or its position changed as may be desired. F is a second riffle, similar in form to E, at lower end of table, with movable gate f in the center. G is a top agitator, shaped to conform with the surface of the table, and is held on the machine by cleats g, and is so connected and held in place by means of slots, as to move in conformity with the various movements of the table. H represents pins extending downward, so arranged as not to interfere with the pins on the main table.

The operation of the machine is about as follows: The material is fed upon the table at one end, and the machine being set in motion, the material is kept in constant agitation by the lateral motion and jar of the machine; the stuff working toward the riffle end f, the tendency being to gather the heavier and more

IMPROVED GOLD-SAVING APPARATUS.

trates, under a less head of water, are allowed to make their way to the end, when the movable gate, already referred to, is removed, the concentrates and other material being easily swept from the machine, with the flow of water and the aid of a broom, into a sluice or concentration boxes, as may be desired.

It is quite apparent that this machine has an advantage that is sometimes overlooked in apparatus of a similar kind used in concentrating—that is, it can be cleaned up completely, whenever desired, thus presenting new and clean surfaces for new material.

AT THE SALT FLATS in Alameda county they usually make about 60,000 tons of salt every year, which is worth about \$10 per ton. The salt product of California is solely by evaporation. Salt cannot be produced on the Atlantic shore as on the Alameda flats, because there is too much rain there throughout the year. And here we cannot compete very favorably with the English product, on account of the difference in the cost of labor and fuel. The English salt is brought over in ships, and there is an immense quantity now on hand.

THE expectation of a heavy wheat crop in California this year is attracting a large number of vessels from all parts of the world. It is expected that the promised high freights will bring so many coal-laden vessels into our bay that the supply will be greater than the demand—and that is why there is a prospect for very cheap foreign coals of all grades. The low prices may prevail throughout the year, unless strikes or other contingencies should interfere.

THE American Pharmaceutical Association Committee reported in favor of the metric system as a basis of weights and measures, and

ELEVATION OF SLAG OUPOLA FURNACE.

SLAG OUPOLA FOR COPPER.

precious particles in the depressed center of the centre riffle E, the lighter particles passing over it, to be again caught by the second or end riffle, when the lighter and poorer sands flow over into a waste sluice, meanwhile, the heavier concentrates being gathered and retained in the central portion of the machine.

For cleaning-up purposes the middle riffle is raised or removed, and the ends and concentrates

were authorized to present a memorial to Congress favoring its adoption.

CHICAGO has formally opened its Mining Stock Exchange,

VALUABLE BOOKS ON MINERALS & MINING

A Practical Manual of Minerals, Mines and Mining. Comprising suggestions as to the localities and associations of all the Useful Minerals; full descriptions of the most effective methods of both the qualitative and quantitative analyses of each of these minerals, and hints upon the various operations of mining, including architecture and construction. By Prof. H. S. Osborn, LL.D. Illustrated by 171 engravings. 8vo, 367 pages. Price.....\$4.50
 A descriptive circular giving the full table of contents of the above book sent free to any one who will send his address.

A Treatise on Metalliferous Minerals and Mining. By D. C. Davies. With 148 illustrations. 12mo, 432 pages. Price.....\$5.00
Drainage. By Stephen Michell. 8vo, 277 engravings. Price.....\$6.00
A Treatise on Earthy and Other Minerals and Mining. By D. C. Davies. With 76 engravings. 12mo. Price.....\$5.00

The Prospector's Hand-Book. A Guide for the Prospector and Traveler in search of Metal-bearing or other valuable minerals. Illustrated. 12mo. Price.....\$1.50
Mineralogy Simplified. Easy Methods of Identifying Minerals, including Ores, by means of the Blow-pipe, by Flame Reactions, by the Spectroscope, and by Humid Chemical Analysis, based on Von Kobell's Tables for the Determination of Minerals, etc. By Henry Ernst, M.D. Illustrated. 12mo. Price.....\$2.00

Underground Treasures; How and Where to Find Them. A Key for the Ready Determination of Minerals within the United States. By James Orton. Price.....\$1.50
 The above or any of our books sent by mail, free of postage, at the publication price, to any address in the world.

Our New and Revised Catalogue of Practical and Scientific Books. 31 pages 8vo, and our other Catalogues and Circulars, including a List of Recent and Standard Works on Metallurgy, Mineralogy, Mining, Assaying, and Chemistry, sent free and free of postage, to any one in any part of the world who will furnish his address.

MINING

—AND—

Ore Dressing Machinery.

By C. G. WAMFORD LOCK.

CONTENTS.—Motive Power—Transmission of Power. Quarrying—Prospecting, Shaft-sinking, Coal-cutting, Pumping, and Ventilating Machinery—Lighting—Hauling and Hoisting Transport—Reducing—Dressing—Miscellaneous.

Price \$21.00. Circulars and Catalogues on application.

E. & F. N. SPON, Publishers.

12 Cortlandt St., New York.

The Explorers' and Assayers' Companion.

A Third Edition of selected portions of the "Explorers', Miners', and Metallurgists' Companion."

A practical exposition of the various departments of Geology, Exploration, Mining, Engineering, Assaying, and Metallurgy.

Price, \$8.00 post-paid. Sold by DREW & CO., Publishers, 220 Market St., San Francisco.

By J. S. PHILLIPS, M. E.

The work is divided into four parts—Rocks, Veins, Testing and Assaying. The geological chapters are intended to give miners a practical idea of the various formations. The chapters on mineral veins are derived from long observation, and the section on exploration has been carefully considered. All that relates to discrimination and assay of minerals has been kept as free from formulae as possible. The work is written for practical men, and all the explanations and descriptions are clear and to the point. It is so prepared that it is useful to uneducated men as well as scientists.

MINING ENGINEERS.

EVERETTE'S MINING OFFICE.

Pioneer Mining Office of the Northwest Coast.

Having the largest permanent brick assay furnaces, chemical laboratory and mining office on the Northwest Coast; with a collection of about 1000 samples of the ores of Alaska, British Columbia, Oregon and the Northwest Territories, and having made personal examinations of nearly every mining camp on the Pacific Slope, from California to Alaska, I am prepared to do any class of legitimate and honest mining work, such as EXAMINING, ENGINEERING, SAMPLING AND REPORTING ON THE VALUE OF ALL MINERAL, COAL AND FIRE-CLAY PROPERTIES, BUILDING STONES, EARTHS, ASSAYS AND ANALYSIS OF ORES, WATERS, ORE, SAMPLES OF ORE, POLLS, "ORGANIC ANALYSIS" WORK, and in fact any work connected with the office of a first-class mining geologist and chemist. Any information mining men may desire to know relative to the MINERAL OR COAL RESOURCES of the entire Pacific Northwest will be cheerfully given. Address Dr. WILLIAM E. EVERETT Consulting Mining Geologist and Chemist, 1315 E Street, Tacoma, Wash.

ROSS E. BROWNE,
Mining and Hydraulic Engineer,
No. 307 SANBORN ST., SAN FRANCISCO.

The instrument represented in the above cut is a new and grand little invention, being designed to save life and limb, and innumerable lawsuits, by doing away with the dangerous operation of digging out wet and unexploded loads where Giant Powder is used in mining. The little instrument crimps the cap on to the end of the fuse firmly and absolutely Water-tight. It is also used for cutting the fuse. They are neatly gotten-up of the finest cast steel, nickel plated, Price, \$2 each, or the entire instrument finished in gold plate, \$5.

WOODBURY ORE CONCENTRATOR WITH IMPROVED BELTS.

More than DOUBLE THE CAPACITY with One-Half Less Power and Occupying Less than One-half the Space of any other Concentrator.

Built of Best Steel and Wrought Iron.
STRONG AND DURABLE.
Price \$575 f. o. b.
Send for Catalogue and Testimonials.

The annexed cut shows the belt in its improved form, which consists of corrugated edges, to form an expanding top edge. This excess in length of material effectually prevents the edges from cracking; plain edge belts have to stretch about one inch to the foot as they pass around the drums. This continuous stretch cracks the edges. The improved belt obviates that difficulty.

GEO. E. WOODBURY, Man'r, 213 to 219 First St., San Francisco.

GOLD MINES —AND— STOCK IN MINES FOR SALE.

Dividend-paying Mines from \$150,000 up.
Undeveloped Mines from \$10,000 up.
Undeveloped Mines on Bond.
Stock in Dividend-paying Mines from \$1 up.
Stock in Undeveloped Mines now being opened from 25 cents up.

All situated in the GRASS VALLEY MINING DISTRICT, the Oldest Quartz Mining District on the Pacific Coast, and the Richest and most Permanent in the World. The mines of this district are practically inexhaustible, as nearly half a century of constant working is proof. Grass Valley has the deepest regular dividend-paying gold mines in the world, and the end is not yet, for these same mines are as rich to-day as at any time during their history.
Gold mining, especially in Grass Valley, when under honest and scientific management, is one of the easiest and most profitable of all American industries. It is a business that will return annually a profit of from 100 to 300 per cent on the investment. Mining is a science acquired only by years of study, combined with practical experience. Therefore, failure is the rule whenever the management is ignorant and unscientific.
The undersigned is a practical scientific and successful miner, has made mining a life study and vocation, is honest and trustworthy, and will not, under any circumstances, recommend or deal in any but valuable paying property and properties that will develop dividend-paying.
No Wildcat Mines; no Sharp Practices; no reasonable chance for loss; Honesty and Square Dealing Guaranteed. Correspondence solicited. Full particulars by applying to

S. B. FOWLER, Supt. Hartley Mine, Grass Valley, Nevada Co., California.

MARSHUTZ & CANTRELL, Sole Manufacturers.

Send for Circulars and Price List.

MARSHUTZ & CANTRELL

The Patentee and Manufacturer cordially invite miners to critically examine and pass judgment upon this improved system of milling and amalgamating ores in the following particulars:

1. The cost is less than one-half of stamps of same capacity.
2. The freight to mine is less than one-half of stamps.
3. The cost of erecting is less than one-fourth of stamps.
4. The power to drive it is less than one-half of stamps.
5. The wear is less than one-quarter of stamps.
6. There is no wear except on shoes and dies.
7. In point of amalgamation it is superior to any other machine in use.
8. In its simplicity of construction.

We challenge competition with Stamps, Ball Pulverizers or any other ore crushing machines now before the public.

IMPROVED FORM OF HYDRAULIC GIANTS.

THE ABOVE CUT ILLUSTRATES THE IMPROVED FORM OF DOUBLE-JOINTED HYDRAULIC GIANTS which we manufacture. We guarantee purchasers of this form of Giants against all costs, expenses or damages which may arise from any adverse suits or actions at law. We are further prepared to furnish Single-Jointed Giants when required. Prices, discounts and Catalogues of our specialties of Hydraulic Mining Machinery sent on application.

IMPROVED BELT FRUE ORE CONCENTRATOR.

The Best Ore Concentrator in the market, having double the Capacity and doing its work as close as the plain Belt machine, while its concentrations are clean. It is used in a number of Mills, the most notable of which is the Alaska M. & M. Co's Mill, where 24 Improved Belt Frues are taking the Pulp from 120 Stamps, crushing 350 tons per day, and is giving entire satisfaction as against 48 plain Belt Machines, taking the Pulp from the other 120 Stamps.

Price of Improved Belt Frue Vanner, \$825, f. o. b.
Price of Plain Belt Frue Vanner, \$575, f. o. b.

For Pamphlets, Testimonials and further information apply at office.

ADAMS & CARTER, Agents FREE VANNING MACHINE CO., Room 15. No. 132 Market Street, San Francisco, Cal.

Protected by Patents December 22, 1874; September 2, 1879; April 27, 1880; March 22, 1881; February 20, 1883; September 18, 1883; July 24, 1888. Patents applied for.

There are Over 2200 Plain Belt Machines now in Use.

THE MONTANA COMPANY (Limited), LONDON, October 8, 1885.
DEAR SIR:—Having tested three of your Frue Vanners in a competitive trial with other similar machines (Triumph), we have satisfied ourselves of the superiority of your Vanners, as is evidenced by the fact of our having ordered 20 more of your machines for immediate delivery. Yours truly, THE MONTANA COMPANY (Limited).

N. B.—Since the above was written the 20 Vanners, having been started, gave such satisfaction that 44 additional Frues and more stamps have been purchased. ADAMS & CARTER.

“TRIUMPH” ORE CONCENTRATOR WITH IMPROVED RIFFLED BELT.

The competitive trials which have been held between the “Triumph” Ore Concentrators, the “Frue” Vanners and other forms of concentrating devices, do not warrant the assertion that the “Frue” Vanner is the best ore concentrator in the market. The fact that the “Frues” have improved (corrugated) belts does not militate against the superiority of the “Triumphs” for, when desired, they (the “Triumphs”) can be mounted with a superior belt known as the “Blasdel” Riffled.

Price “Triumph” Concentrators, with Improved (Patented) Belt - - - \$650 f. o. b.
Price “Triumph” Concentrators, with Plain Belt - - - - - \$550 f. o. b.

We are prepared to guarantee the superiority of the “Triumph” over the “Frue” or any other form of Concentrator, for coin if need be. Circulars and testimonial letters furnished on application.

(PATENTED).
Both the “Triumph” Concentrator and “Blasdel” (riffled) Belt are protected by incontestable letters patent, granted by the Government of the United States.

Original Empire Mill and Mining Company,
Principal Office, 401 California St., cor. Sansome, S. F.
Location of Works, Grass Valley, Nevada Co., Cal. }
GRASS VALLEY, NEVADA CO., CAL., Nov. 10, 1885.
Joshua Hendy Machine Works, 39 to 51 Fremont St., S. F., Cal.:

GENTLEMEN—I am pleased to state, in reference to the “Triumph” Ore Concentrators, that four (4) of them were placed in the mill of the Original Empire Mill and Mining Company in April, 1884, and a thorough test made of their practical operation; and their efficiency having been demonstrated, four (4) more were subsequently introduced as the complement of the Twenty (20) Stamp Mill, and the eight (8) have been and are now running with entirely satisfactory results.
At the Ten (10) Stamp Mill of the North Star Mining Company, under my supervision, four (4) are also in successful operation, and from my observation of their practical working, I am convinced that this form of Concentrators is the equal, if not superior to any other style of Vanners or concentrating devices.
(Signed) Sup't North Star and Original Empire Mining Co. DAVID McKAY, JR.
N. B. When the stamping capacity of the two above named mills was increased, more “Triumph” Concentrators were purchased, and twenty-eight (28) are now in constant successful operation.

THE PELTON WATER WHEEL

GIVES THE HIGHEST EFFICIENCY OF ANY WHEEL IN THE WORLD. OVER 1300 IN USE.

Affords the most simple and reliable power for all mining and manufacturing machinery. Adapted to heads running from 20 up to 2000 or more feet. From 20 to 30 per cent better results guaranteed than can be produced from any other wheel in the country.

ELECTRIC TRANSMISSION.

The advantages the Pelton Wheel affords in the way of a uniform and reliable power, close regulation, and the facility of adaptation to varying conditions of speed and pressure, have brought it into special prominence and extensive use for this class of work.

All applications should state amount and head of water, power required and for what purpose, with approximate length of pipe line. SEND FOR CATALOGUE.

THE PELTON WATER WHEEL CO.
121-123 MAIN STREET, SAN FRANCISCO, CAL., U. S. A.

PELTON WATER MOTORS, Varying from the fraction of 1 up to 15 and 20-horse power, unequalled for all light-running machinery. Warranted to develop as given amount of power with one-half the water required by any other. SEND FOR MOTOR CIRCULAR. Address as above.

THE GATES ORE AND ROCK BREAKER.

UNLIMITED IN CAPACITY, UNEQUALED IN EFFICIENCY, UPWARD OF 3000 NOW IN USE.

Will do more than twice the work of any other with the same cost in wear.

Gives a fineness of product that increases the capacity of any mill from 25 to 40 per cent without any additional expense. THE BEST AND ONLY CRUSHER ADAPTED TO MACADAM ROAD WORK. Send for Circular.

THE PELTON WATER WHEEL CO., 121-123 Main Street, San Francisco, General Western Agents.

THE NEW ARMORED COAST DEFENSE VESSEL MONTEREY.

The Cruiser Monterey.

Description of a New Floating Fort.

An engraving is given on this page of the new double-barreled, twin-screw, armored coast defense vessel Monterey, launched last week from the yard of the Union Iron Works, in the presence of President Harrison and party.

Mrs. Harrison touched the electric button which released the vessel from the ways. The Monterey is a two-sided vessel, as her picture shows, but she is powerful and strong, being well equipped for coast and harbor defense.

The contract for the construction of the vessel was awarded to the Union Iron Works June 4, 1889, and she makes the third man-of-

war of the new navy launched from the ways of that enterprising firm.

The general dimensions are as follows: Length over all, 261 feet; load water line, 256 feet; extreme breadth, 59 feet; mean draft, 14 feet 6 inches; displacement, 4000 tons; displacement in fighting time, 4486 tons; armor belt amidships, 13 inches thick; indicated horse power

of engines, 5400, estimated speed, 16 knots.

The Monterey is constructed entirely of steel and has a double bottom throughout, there being 110 water-tight compartments in her hull that can readily be filled with water, submerging the vessel until only about one foot of her sides shows above water.

The Mines of Amador County.

[From Our Traveling Correspondent.]

EDITORS PRESS:—Amador makes no display, in fact is so very conservative that she does not receive the credit due her. To the old-time mining operators it is a well-known fact that the mines of Amador have produced a greater amount of gold than the same class of mines in any other county of the State. Amador not only has done this in the past, but the mines are still at it with a regularity and extent of dividends that challenge comparison. While the past and present are very satisfactory to all parties concerned, the near future promises to excel the past. Here, as everywhere, a new life has been infused into the mining industry, and instead of the old-time disposition to work only well-known mines of undoubted worth, a new era has been entered on and the old mines are being given a general searching for the hidden treasure, while numerous mines that had been superficially scratched over in times past are now either being developed or in a fair way to be.

This willingness on the part of mining capitalists to put money into a hole is due to the fact that a large amount of money not only has come but is to-day coming out of some of the "holes" in old Amador.

The county claims the distinction of having at this time a mine—the Kennedy—that pays the largest regular dividends of any gold mine in the State. That the Kennedy will equal, if not excel, the Old Keystone seems now a foregone conclusion, while other mines will soon follow her in the race for supremacy.

Plymouth.

At Plymouth, the Old Plymouth mine, under Mr. W. T. Jones as superintendent, has been undergoing a continuous system of exploration, with good ore in sight. From the 1245-foot level a drift has been run 1100 feet into the Indiana ground and a vein 15 inches wide of very good ore encountered. Twenty stamps of the old mill will be dropping on this ore, and should the vein widen to 30 feet, as it usually has done, it will only be a question of time until all 60 will be pounding away to show that the Old Plymouth still has an abundance of the yellow metal stored away for those who will persist and insist on finding it.

Bay State.

(W. T. Jones, promoter). This old mine is located in Enterprise district, three miles north of Plymouth. Its worth is so well known that Mr. Jones has succeeded in securing subscriptions to almost all of the stock from the citizens of Plymouth. In this way, without waiting for outside capital, the people of the town propose to develop and equip the old mine and reap the benefits themselves. If other mining counties would adopt the same plan, many a mine of known value would soon be declaring dividends, while the wildcat schemes in the same sections, that are heavily capitalized, drag out a lingering death, by continuous assessments, and finally close down.

New London.

E. Jones is superintendent of the New London. A drift is being run on the 1000-foot level, the mill, in the meanwhile, being closed down.

Amador City.

The Grover M. Co., J. Call superintendent, is opened by two shafts, 700 and 1000 feet deep. At this time the ore is coming from the third, sixth and seventh levels. The vein averages 15 feet in width of quartz that carries three per cent of \$90 to \$100 a ton sulphurets, while the ore averages \$5 a ton. The mine is equipped with a fine 20-stamp mill run by water power. In addition to the water power, the mine has a 50 H. P. Edison motor and dynamo for the pumping plant.

Bunker Hill.

J. Myers is superintendent of this company. They are putting down a new three-compartment shaft on the May Flower end of the property. The shaft is now down 200 feet, with a drain tunnel, 1100 feet long, run and connecting with it. Ore is taken out through this tunnel to the mill. In the old Bunker Hill workings, the mine is opened to a depth of 800 feet, with levels run 1400 feet, all in ore. The quartz carries 3½ per cent of sulphurets worth \$55 to \$60 a ton, while the average value of the vein matter is \$4 a ton. The vein runs from 10 to 12 feet in width. The mine has a 40 stamp mill and its own barrel-process chlorinating works.

The Keystone.

E. C. Hale, formerly on the Comstock, is superintendent. The Keystone is opened to a depth of 1200 feet vertically, or 1573 feet on the vein by two shafts. At this time 20 stamps are running on quartz coming from the upper levels, the work being in a manner of a prospecting character. In the lower workings, the quartz is not considered sufficiently high in value to work. The Keystone at 1573 feet has encountered the same barren ground that the Idaho struck at 1600 feet. In the Idaho it was only a question of going 300 feet deeper, through barren vein matter, until the mine got back to old-time values, and has remained there since.

From the large amount realized in the past

from the Keystone, it would seem that a few hundred feet more in depth would be not giving a good mine the development it has earned, and there is little, if any, doubt that the mine in depth will get back to her old habit of steady dividends. The Keystone is one of the oldest and best mines in the county, thoroughly equipped in every way. To date the mine has yielded \$3,379,992.49, and paid dividends of \$3,737,800.

South Spring Hill.

J. R. Tregloan is superintendent of the Spring Hill. The property is being given a general overhauling, not alone in the mill, but the mine as well. Its close proximity to the famous Keystone (which it adjoins on the south) coupled with the able management of its well-known superintendent, make it more than possible that this mine will tally the Keystone. The mine is now opened to a depth of 900 feet by two shafts, with drifts run 1500 feet on the vein all in pay ore. The vein averages 12 feet in width, though it is not unusual for it to swell to 50 feet. The ore carries one to two per cent of sulphurets that average \$90 a ton, while the vein keeps up in value with its width by giving its owners a steady product of \$10 a ton. The mine has a complete water or steam mill of 40 stamps, crushing 2½ tons a day to the stamp.

The works are lighted by the company's electric light plant. The company has recently added ten stamps to the mill, with additional concentrators, and purchased additional property, giving them 60 acres on the mother lode, 3000 feet on the vein, and 1300 feet on another, all from the earnings of the mine, which is now in condition to pay regular monthly dividends from this time on.

Amador Reduction Works.

Voorhes & Barney are the proprietors of these works, which are midway between Sutter creek and Amador City. The main works form an extensive chlorination plant, probably the largest and best equipped of any chlorination works on the coast. At this place, four tons of sulphurets are treated each day at a charge of \$20 a ton, less 10 per cent, on low-grade sulphurets, for loss. The Amador Works received the personal charge of Senator Voorhes. In addition to this plant, the owners also own the Phoenix Reduction Works at Drytown. The Phoenix is in charge of Mr. Barney. While these works are not as extensive as those of the Amador, still they handle three tons of sulphurets a day, and work them as close as the Amador. In addition to these works, the Zeile, Kennedy and Bunker Hill mines have each their own chlorination works.

Knight's Iron Works

Are located at Sutter creek. These works furnish the larger part of the machinery for the mines of Amador county. They could not do so, if the work turned out was not the equal of any other works. In the near future, Mr. Knight will take his light from under the present bushel, and illuminate the advertising column of the PRESS with the same.

Sutter Creek.

The Old Mahoney is now incorporated as the Hector G. M. Co., with S. D. Valentine as superintendent. Mr. Valentine is giving the Old Mahoney an awakening, and with time will put her on the list of dividend mines of Amador; 5000 feet of 15-inch pipe is now being put in to connect the mine with the Amador canal, and change the works to water-power, and new hoist is being put up to develop the mine. In the meanwhile, 40 stamps will be started up on surface rock. The old shaft is 1000 feet deep. There has never been any question as to the mine's value, and now that it has fallen into the hands of the Valentine Bros., there is no doubt of their making a success of it.

The Lincoln.

The Lincoln (S. Moyle, Supt.) is now being operated by the administrators of the Stewart estate, who are confining themselves to the surface ore, which averages \$2.50 a ton; 20 stamps are dropping. It is the opinion of the mining superintendents of the company, that this property only wants capital and competency to make a mine of it.

The Summit.

J. Tregloan & Son are owners of this property. It joins the famous Enreka on the south. The vein crops 50 feet wide in ore that has gone from \$18 to \$35 a ton. Messrs. Tregloan intend to incorporate the mine. With the success that has been the lot of father and son in the Spring Hill and Wildman, there is no doubt of their making a success of the Summit.

The Wildman.

On the Wildman, Mr. John Tregloan, the superintendent, has shown what can be done with an abandoned, worked-out (?) mine. He now has the shaft down 800 feet with drifts run 400 ft. on the vein, which runs from one to 50 ft. in width, carries from 1½ to 2 per cent of sulphurets that run from \$65 to \$120 a ton; while the ore averages \$6.25 a ton. The mine is equipped with a fine 30-stamp mill, crushing 65 tons a day. The mill and works are lighted by the mine's electric light plant. Mr. Tregloan has brought his long experience in mining to bear upon the property as is shown by the numerous appliances for the rapid, economical and effective working of the ore. While the company has expended over \$40,000 in the equipment of the mine, this and a dividend of \$12,500 has been paid back out of the proceeds of the mine in the short time that Mr. T. has

had it in operation. If further proof were needed of the mine's success, a handsome retort of gold that kicked the beam well up in the thousands was on the scales at the time of my visit.

The Kennedy

Is to-day the leading mine of the county—paying very large monthly dividends, in fact the largest of any mine in the State. The superintendent, Mr. J. T. Parks, is one of those conservative men, who, while exceedingly kind and unmanly courteous, prefers in his modesty, to say nothing of himself or the mine under him. It is but due the mining public to say that Mr. Parks is regarded by the mining superintendents of the county, as the best mine superintendent in the county and these same superintendents insist that the fact that the Kennedy's last monthly dividend was for \$40,000 should be known, so we give it and beg pardon of Mr. Parks for so doing. The Kennedy is opened by two shafts, the north, 1350 feet and the south 1250 feet deep. The vein has been drifted on for a distance of 1600 feet, with an average width of four feet. In the pay chutes the vein very accommodatingly swells to 20 feet in No. 1, to 10 feet in No. 2 and three to four feet, in the other two shoots. The ore carries 1½ per cent of sulphurets of \$100 to \$175 a ton value, while the vein matter runs from \$12 to \$15 a ton. The mine has a complete 40-stamp mill, and three tons a day chlorinating works. With dividends of \$40,000 a month, it does not require a prophet to foretell that the Kennedy is going to press the old Keystone very hard in the millions.

It is not anatomy for me to say aught personally of the superintendents of the mines, but in Mr. Park's case, I would like to digress and state that he is not alone an experienced mining superintendent, but a gentleman in the truest sense of the word.

The Zeile.

The Zeile is down 1160 feet, with drifts run 940 feet on the vein, which has an average width of 30 feet of quartz that carries 2½ per cent of sulphurets averaging \$100 to the ton, while the vein matter averages a little less than \$4 a ton. This, under Mr. W. T. Detert's management, is mined and milled for \$3 a ton. The mine has a 40 stamp mill, crushing 140 tons a day, and a chlorination plant of three tons a day capacity. The hoist is run by steam and the mill by water power.

The Amador G. M. Co., Limited, property, pending litigation, is closed down.

Irish Town.

On the Climax, Reed & Huskey owners, a tunnel is being run 450 feet to the vein. While this tunnel is being driven the 10-stamp mill is idle. The Climax is well known for very rich specimen rock.

Clinton Con. M. Co.

This company is working the Clinton and McCardo with two mills of 10 and 20 stamps. The mine is opened by a tunnel 1000 feet long that cuts the vein 200 feet deep. The vein is very large, running up to 25 feet, and carries a large per cent of sulphurets that go from \$150 a ton up, with the vein matter running from \$5 to \$50 a ton. The mines are under the charge of Mr. John B. Francis and Wm. Floyd. While but little is heard of this section, notwithstanding the fact that the Clintons are dividend mines, the coming season promises to show up a number of good properties in addition to those already developed. Amador has done well in the past. She is doing well in the present, with every evidence of doing still better in the future.

The mines are almost all of them on the mother lode, and in a section where the vein matter of the lode averages higher than in any other county, thus assuring permanency, size and value to her quartz veins, from which naturally follows the large dividends for which Amador county's mines are famous.

E. H. SCHAEFFLE.

A Gold Bismuth Ore in Arizona.

EDITORS PRESS:—Under the caption of "a peculiar occurrence of gold" you quote in your issue of April 11, an interesting article from the *Engineering and Mining Journal*, written by Mr. C. H. Aaron. In it a description is given of certain small mineral veins in Honduras, which carry gold and bismuth. I send you a sample of ore from one of my discoveries in the Doa Cabezas Mountains, in southeastern Arizona which you will find rich in both of these metals. It comes from a very large vein, but occurs only in spots in the common ore, which contains a good deal of talc and magnetic iron.

To save the gold in assaying this ore requires great care. There must be a free use of litharge and lead, and if the muffle gets too hot, the "button" will suddenly disappear, leaving only hundreds of almost invisible globules of metal on the top of the anvil. Many noted assayers have certified that ore of this class which I sent there for assay contained only "a trace of gold," or they gave a dollar or two per ton as the accurate product. Since I could get sufficient free gold in the horn-spoon to prove that the very one they had treated contained \$40 to \$50 to the ton, I ceased to put confidence in such certificates.

When I made one or two shipments of selected ore to well-known smelting works, and was paid for them under assays varying from \$187 to \$237 per ton, with scarcely any silver, I con-

cluded that my horn-spoon tests were more trustworthy than the assays I had been getting.

The assayers at the reduction works where the ore was sent, being warned as to the care necessary in assaying it, appeared to get along very well. There is visible gold in the fragment of ore I mail, and, if properly assayed, it will be found of high grade.

Perhaps Mr. Aaron's allusion to "the well-known expansion of bismuth at the moment of solidification after fusion" may explain to some extent why under certain conditions the gold in assays made of this ore vanishes from the anvil. The cooling of the bismuth in the bone ash may produce sufficient expansive force to throw the "button" in a thousand directions. If that should be the case, then the overheating of the muffle may not be so fatal to an accurate return, as the leaving of the button too long in the cupel would prove to be.

JOHN DARE EMERLEY.

Dos Cabezas, Arizona, April 23, 1891.

Placers of Sonora, Mexico.

NUMBER IV.

EDITORS PRESS:—Since my last communication, I have learned that certain parties in this city claim all right and title to the placers of Los Llanos and La Cienega, State of Sonora, Mexico. As I have already stated that the titles obtained by Samuel and Charles M. Tyler from the State of Sonora for the above districts were not considered good and sufficient, an explanation may be necessary and save considerable time and expense to others, who may have any idea or intention of holding the above grounds in fee simple.

I have before me two maps, made of the two placers, drawn from the field notes of surveys, and made for us by the Perita de Minería, who is a federal officer or surveyor, appointed by the Government to inspect, measure and deliver vein and placer claims to the parties denouncing them.

These surveys were made at our request and with all the formalities required by Mexican mining laws. Now, although the documents are on stamped paper (which, by the way, is required on all documents made in that country, to render them legal), the grounds formally delivered to us, under the endorsement of the Governor and Secretary of State, I still consider the title worthless. They require the approval of the Federal Government of Mexico, the same as our laws require a Federal patent on mines, to hold them free from denouncement, when idle or not worked within specified times. Yet they can be worked in the manner I have stated, by working out one claim and taking up another, or by a number taking up claims so as to have ground enough for formal operations.

As the State title we held was for about 56 square miles in the Cienega district, and about 42 square miles in the Llanos, it looked at the time like a very good thing, and might even yet lead an honest miner into an operation or an enterprise, that would prove a "delusion and a snare;" I of course allude to the title.

In any event, the extent of placer ground is majestic and grand; for, if we take their area to be 60 square miles, something over one-half of what was granted, it can be demonstrated that it would take nearly one-half a century for 100 machines of the capacity of 600 tons per day to exhaust the ground. This is allowing 26 days per month and the dirt to be five yards deep.

Again, it can be demonstrated, as I have already stated in a previous article, that there were one hundred millions remaining in the two placers. I should like to say that one hundred and sixty millions would not cover the amount in the two districts. Of course, all this is theoretical, and yet it is a long way from the impossible.

In presenting the following traditional and legendary lore of Los Llanos and La Cienega and which is the common talk of Northwestern Sonora, I do so with the idea that the tales are fully as reliable as the stories of the millions sunk with the steamer Brother Jonathan on our northern coast, the wrecks of the Galleons in Vigo bay, on the coast of Spain, with their millions, and many other accounts that are yet to be proven.

During our stay among the placers another subject took up our attention, and while but little fact and a great deal of fancy and romance were established, it was and is still an interesting study.

What the deuce had become of all the gold taken out?

It is related that Don Teodoro Salazar, the discoverer, made his headquarters in about the middle of Cienega, where he put up an immense building for himself, including buildings for storehouses, and a hacienda for working the rich quartz croppings of La Mina de Salazar and La Mina Teodoro.

Salazar, it seems, was a stately Spaniard, without relatives in Mexico, rich in cattle and lands, and with all that contempt for races not white, so characteristic of the Spaniards, who is said to have taken a cool, calculating advantage of the miners in every way. Having hundreds of employes of his own, Mexicans and Yaquis, and immense stores of dry goods and provisions which he retailed at prices ruinous to purchasers, and to all who came in his way, his

commercial transactions must have produced fabulous returns.

This together with his being right in the beginning and middle of the bonanza of both placers, the absolute way he had among all classes, the hundreds of servile peons of his own, whose earnings were daily poured into his coffers, gave the impression that his wealth in gold alone, reached well up in the millions.

About 1820, having reached well into the allotted span of man, he sent for the priest of the church of Cienega for confession and absolution, exacting a promise that in regard to his wealth, nothing should be said before his death.

The priest's story, told after the demise of the old Spaniard, was that when the services of the church for the remission of sins had been performed, he, in a sociable and friendly way, asked the old man in regard to his great wealth, and whether he might antedate some hope that his church would not be forgotten in the way of a donation. That in reply the old man assured him that the church should not be forgotten, and then leading him through several rooms to one located near the center of the building, he, with some effort, unbarred and unlocked a great door, disclosing a room completely in the dark. Producing a light, he opened great chests, at least ten in number, which were absolutely stuffed with gold, both in sacks and loose, both fine and coarse, some of the lumps the size of goose eggs and down to hokory nuts, beans, corn and lentils, down to bags of dust. Returning, Don Teodoro presented the good father with ample means to thoroughly renovate and redecorate the church. Since that one interview, he never was invited to the house again, nor allowed in any way to ever open up the subject with the old Spaniard, who, so the story goes, died about two years afterward.

It was not long after this latter event, when it can readily be imagined, that an industrious and persistent search was made for all this hidden wealth, but without success. Not one trace of the old Spaniards hoarded millions has been met with from that day to this. Every cave and nook for miles around Cienega has been prospected and overhauled, the ruins of the old building dug up and every rumor traced.

Then superstition was resorted to, or came naturally, particularly among the class of which I am writing, and it was asserted that the shade of the departed Don was seen to be walking among the ruins of his buildings. His stately walk, his black, brocade suit and silk hat, all appearing as in life, and that his walks generally took place on moonlight nights. However, this latter notion was effectually squelched by Salvador, a Papago, and one of our workmen who, brave as a lion and lithe as a leopard and with love of gold fully developed, frequently took his serape, tobacco and machete, and amid the lonesome ruins, "camped on the trail" of the old Spaniard, and of course without meeting him. (This is an actual fact; Salvador in describing the idea to me, stated in fair Castilian, that it would take a much warmer place than Cienega to stop him from learning something of the treasure if he once got his eyes on the "spook.")

Personally, I felt considerable disappointment when I found that the little lake in the town had been cleaned out to free it from the grass and weeds encroaching upon its surface. I should have readily joined in pumping it out, as the gold fever is quite contagious.

Knowing the faithfulness of the poor despoiled peon, it is my opinion that with the assistance of some trusted ones, Don Teodoro packed the gold away, and buried it at some considerable distance from Cienega, and probably, which is a horrible thought, the poor peons never returned to tell the tale.

At the Llanos, at the local placer named on the map La Barraca, the sands are very deep (said to be 50 feet to bedrock), and which are of a flowing nature; we were told of an accident to the miners in the early days, that has kept them from attempting to reach bottom ever since. It is told that in the early periods the surface grounds of the Barraca were quite rich and an attempt was made to reach bedrock. In their primitive way, the miners designed quite a large surface opening, which was to taper gradually in the shape of an inverted cone while sinking, with a view to stop the running sand. Bottom was finally reached, and a few yards of it exposed, showing, so the story runs, a bedrock literally covered with gold nuggets. The excitement was so great that a rush was made from the adjoining claims, when the sand started to run, leaving four miners buried on the bottom.

Now, while we had every confidence in our ability to bottom the claim, with a orbed sinking shaft, such as we built at Cienega, the story was too rich, and with the many other affairs we had on hand, we could only look at it theoretically, and leave to future explorers its accomplishment.

At La Plateida, marked on the map of Cienega, we were shown ground where it was said to have been so rich that a great many were killed in the fight made to dispossess the more fortunate ones of their claims.

Of Celis Island, just off the eastern coast of the Gulf of California, lying but a few miles from shore, near the port of Libertad, some very strong stories are told of the gold and silver to be found there, the placers being hardly touched. The Celis Indians, who are the sole owners and inhabitants, and about 500 in number, are a savage, warlike race, and will not permit any interference in their

affairs—so much so that Mexico has not been able to get them under control. As I saw about 30 of the Indians give an exhibition of their ferocity and warlike ability while on their way to treat with the Governor of Sonora on some local differences in regard to the management of their fisheries, it was a natural conclusion on my part to let some one else take their island.

These stories might be continued for pages and are only given that the wheat may be separated from the chaff; yet they form a part of the accounts already given, and in a way, show the favorable estimate the natives have of the placers I have already described. At the same time many stories, tales and traditions have led to prospecting and researches that in a number of cases have turned out grandly, as witness some of the mining ventures in California, Nevada, Arizona, etc.

The placers, in my opinion, are quite good enough as they are for economical handling with capital, and should any of the many rich stories about them prove true, they would simply add to their value as already known to-day.

CHARLES MARION TYLER, M. & M. E.

Terrorite.

A New High Explosive.

Terrorite is a high explosive which is claimed to be more powerful than high-grade dynamite and safer to handle than gunpowder. It is applicable to all purposes where a high explosive is desirable, such as destructive blasting, shooting, oil wells, etc., and its safety in handling makes it especially valuable for use in warfare and for engineering purposes. A Russian Company, with headquarters in this city, is corresponding with the naval authorities at Washington for permission to experiment with Government guns. They are also trying to arrange with one of the San Francisco powder companies, not now manufacturing, for the use of their plant for making this new explosive.

The use of terrorite does not require any change either in the guns themselves, the projectiles or the fuses. The shells may be filled with the explosive and the apertures closed with wooden plugs, or the fuses can be screwed in at once and the shells kept in storage.

The Mexican Consul in this city called the attention of his Government to this new explosive, and at President Diaz' invitation the chemist sent from here and manufactured a quantity of the powder for experimental purposes. By order of the Minister of War, a Board was convened to test the powder.

The shells used in the experiments were ordinary ones, such as would be utilized with powder charges, and were fitted with American and French fuses.

Before the Mexicans ventured to load the cannon with shells filled with Terrorite, the shells were subjected to the following test in order to determine their insensibility to shock: Three shells, eight centimeters diameter, each containing 180 cubic centimeters of the explosive, were closed with wooden plugs, and thrown from a height of 50 meters, then from an elevation of 82 meters, striking the stony bed of a river. None of them exploded.

Then six shells with concussion fuses were fired from a muzzle-loading howitzer, and nine shells were fired from a French breech-loading steel gun. Three shells fired from the gun were without fuses and burrowed into the ground, without exploding and uninjured. The other six shells smashed against the various targets of wood, earthwork, granite and cast and wrought iron, demolishing them into small fragments. The new explosive is smokeless and has been adopted by the Mexican Government. The tests and experiments extended over several months, and only after all the advantages were fully demonstrated did the Government acquire from the inventor the right to manufacture and use the explosive.

The qualities of terrorite are thus stated by those interested in its manufacture in this city:

1. Its explosive force can be regulated at will. In its most powerful form it is four to six times as powerful as ordinary commercial dynamite.
2. It is not affected by shock, jarring, jolting or other mechanical influence.
3. When exploded it is smokeless.
4. It does not explode by the direct application of fire, but burns steadily until the heat developed exceeds 260 or 280 C.
5. It remains chemically stable, and does not lose any of its properties by prolonged storage.
6. It can be made of any consistency desired, from the semi-fluid to the plastic, like clay.
7. It does not disintegrate in contact with iron, copper, brass, zinc, tin or lead.
8. Frequent changes of temperature, even below the freezing point, do not affect its explosive force.
9. It is especially valuable for use in artillery, as it can be fired with a powder charge, while the containing shell is shattered into small fragments. The fragments of the shell are hurled with terrific force in all directions, and cover an area several times greater than that effected by the explosion of an ordinary powder-filled shell. Furthermore, as the fragments of the shell are small, the effect in the

enemy's ranks must be proportionately more destructive.

10. It may be used for loading all kinds of shells, and no change in the guns, their loading mechanism, the shells, or fuses is required.

11. By its great explosive power, its safety in handling and its chemical stability, this explosive is eminently adapted for charging torpedoes and all kinds of submarine mines, either stationary or movable.

12. In naval warfare, this explosive stands unrivalled. A shell filled with it can be made to penetrate the armor of an iron-clad before explosion, and even if the penetration is only a few inches, the explosion will cause enormous damage.

Prof. Lemmon's Report on California Conifers.

The botanical portion of the 1890 report of the California State Board of Forestry is commented upon by *Garden and Forest* as follows:

An account of the true Pines of California appeared in the Second Report of the Board of Forestry of that State from the pen of the botanist of the board, Mr. J. G. Lemmon, who now supplements this with a paper on the other coniferous trees of the Pacific forest, which occupies the larger part of this third report and which is enriched with many admirable illustrations made from photographs of trees, forest-scenes, and fruiting branches of many of the species. In this paper, after some remarks upon conifers in general, their history and distribution, Mr. Lemmon describes their classification, and then proceeds to give an account of the different species (exclusive of the Pines) found in California, and in the regions of which California must be considered, from the botanical point of view, an integral part, that is, all the great territory of western America which extends north and west of the State. An account of the different species is preceded by notes on the genera to which they belong, and to this is added some information relating to species which occur entirely beyond the region. In the case of the Hemlock, for example, there is a short account of our eastern species, and of the Asiatic species of this genus; and under the Spruce, not only are the Pacific coast species described, but the White and Black Spruces of the east as well, the European Spruce, and some of the Japanese species. Changes in the generic and specific rank of a few trees are proposed. The Alpine Hemlock is here removed from Tsuga and made to compose the genus *Heopropence* (Engelmann's sectional name), a genus characterized by Mr. Lemmon by its alpine habitat, its cones, which are longer than those of any Hemlock Spruce, oblong-cylindrical, and two to three inches long, with numerous scales, nearly all of the same size, and reflexed at maturity, broader than long, four to eight lines wide, and striate with a thin, wavy, rounded border; by the small, spatulate bracts three to four lines long, by the angular seeds with resin vesicles, and elliptical wings three to six lines long, and linear scattered quadrangular leaves keeled above and below with a solitary and large resin duct. "The propriety," he says, in speaking of this tree, "if not the scientific necessity, of separating it from Tsuga may be justified upon the ground that the conifer family is so large, and the necessity for dividing it into groups for convenience of comparison is so apparent, that comparatively slight differences (so they are fundamental) must be taken for generic distinctions"—a view of genera in which, we fancy, all students of conifers will hardly concur.

The large-cone Douglas fir of the mountains of Southern California, which Engelmann considered a variety of the widely distributed *Pseudotsuga taxifolia*, is now restored to specific rank under the name of *Pseudotsuga macrocarpa*, because the author recognizes "in it elements that certainly point to such separation. It must be borne in mind," he remarks, "that the evidence of distinctness does not depend so much upon the number of characters as upon their permanence. Now the characters of this spruce are always uniform—no transition trees connect it to the other species; again, the other species is both north and south of it, particularly north. If this big-cone development is a recent variation, what has produced it? If a southern climate, why are not the Arizona and Mexican trees still larger coned? If a dwarf variety, why so prolific in fruit?" Mr. Lemmon, in a note, calls attention to the fact that when he visited the headquarters of this tree, in the San Bernardino mountains in 1876, "the cones of the preceding year's crop lay on the ground so abundantly that they were two or three feet deep under the trees—a degree of fecundity never observed in the taxifolia species."

The red fir of the Sierras (*Abies magnifica*) is well described, and the variety of Northern California, which so long puzzled botanists by its long, exerted cone-bracts, resembling those of *Abies nobilis* of Oregon, is described as the variety *Shastensis*. The peculiarity of this variety of fir, aside from its locality, is connected entirely with the fact of its cone-bracts becoming long and protruded, a half to a full inch between the scales, rendering the large purple cones, thus decked out with tasseled fringes, a most beautiful object. The trees of this variety, Mr. Lemmon tells us, are "very large and lofty, though not so immense and high-headed as in the typical southern form, but they become, on the southern slopes of Shasta,

a dark, gloomy assemblage of massive black trunks, colored on the north side, from base to the limbs, with bright yellow lichens or tree moss; the lower limbs draped here and there with long sweeping festoons of black, filmy lichen, giving a inneral aspect to the whole scene, scarce relieved by the twitter of a red squirrel, the long, wailing note of a woodpecker, or the occasional cry of a bald eagle."

A second variety of this species is distinguished as variety *xanthocarpa*—"a smaller, less symmetrical tree than the typical, with smaller cones averaging four to five inches long, half as thick near the base, tapering slightly to the apex, and of a yellowish color." It is found in the high Sierras around Meadow Lake, Sierra county, where, Mr. Lemmon tells us, it forms the greater part of the noble forest of that region.

Mr. Lemmon considers the white fir of the Sierras and of the mountains of Southern Oregon simply a somewhat modified form of *Abies grandis* of the Northwest coast "distinguished by having a rather rigid habit, the branches relatively shorter and stouter than those of *Abies grandis*. The young shoots are olive-green, the buds ovoid, the leaves dark-green above, whitened with stomata below (also with a few rows above), the leaves relatively very long—one and a half to two inches—nearly all of the same length, obtuse at the apex, not usually two-ranked except on lower branches, yet all are twisted half around at the base, which allows the light to reach through to the branchlets past the distorted leaves. It is, in fact, midway both in locality and in characters between the green-leaved and green cylindrical-coned *grandis* of the moist northern forests and the white-leaved and light-green elliptical-coned *concolor* of the southern arid interior regions." It is this tree which is called *Abies Lowiana* in English plantations, and which, from a horticultural point of view, is very distinct from the species of the Northwest coast, although hardly distinguishable from the long-leaved form of the Rocky mountains.

It is not quite clear whether our author intends to consider the California Sierra tree one variety and the Colorado tree a second variety or not. He adopts for the California tree the name of *Abies grandis*, variety *Lowiana*. If he considers it distinct from the *Abies concolor* of Colorado, he seems to be the correct name; but if he holds that there is really but one mountain form of *A. grandis* worthy of a distinct name, then this should be known as variety *concolor*, it having been named *Abies concolor* before the name of *Abies Lowiana* was bestowed upon it.

Mr. Lemmon, in his very full and interesting description of the Big Trees, raises an interesting point as to the origin of the name Sequoia. The name was made by the Austrian botanist Endlicher, who published the genus in 1847, but, unfortunately, did not give the etymology of this name. It has been generally supposed that it was formed from the name of the half-breed Cherokee Indian, Sequoyah, a man distinguished in having invented a syllabic alphabet for his tribe. Gordon, however, in the second edition of his "Pinetum," published in 1875, states that the name was probably formed from "sequence, separated or following in order of succession after Taxodium, from which Prof. Endlicher separated it." Mr. Lemmon now says that Prof. Gray, at the time of his visit to the Pacific Coast in 1877, informed him that "the report of its being derived from Sequoyah the Cherokee was doubtless an afterthought; that undoubtedly Endlicher derived his name from sequi or sequor, alluding to the well-known fact that our redwoods are the followers or remnants of several colossal extinct species."

Further investigations do not throw much additional light on this subject, and the answer sent in reply to Mr. Lemmon's inquiries by a number of distinguished men are not very satisfactory in their conclusions. The venerable De Candolle writes: "The supposed origin of Sequoia from Sequoyah or Sequamal is entirely fanciful. By the appearance of the name it is probable that it originated from or was taken up from some native word and written more or less correctly. Historically, it is a matter of regret, of course, that any doubt rests upon the origin of the name of the two trees which surpass all others in size and in the interest attached to the history of the genus to which they belong; but, after all," as De Candolle writes, "it matters little—a name is a name. The essential things are, first, that it be the expression of a natural genus; second, that it has not been employed before; and third, that the genus has not previously received another name."

Mr. Lemmon's paper contains, in convenient and acceptable form, a great amount of useful and interesting information, botanical, historical and economic, relating to the trees which compose the larger part of the Pacific Coast forests, and which make these forests the most wonderful and important forests of conifers known to man. It will be welcomed by all serious students of American trees, and will take its place in the permanent literature of the subject.

[We recently stated that copies of this report can be had (sending 10 cents to pay for mailing) by application to Prof. J. G. Lemmon, 1015 Clay St., Oakland. He can also supply a limited number of the Report of 1889, which contains his essay on the Pines of the Pacific Coast—not the "prince" of the Pacific Coast as the '90 had it in our issue of April 18th.—Eps. Press.]

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

SOUTH EUREKA.—*Ledger*, May 2: The hoisting works, rope, etc., and boiler and engine of the Ilex mine in Calaveras county, have been purchased for this property. These works are in splendid order, and were secured at a bargain. It may be a week or two before the work of taking them down will be commenced, and they will be immediately thereafter removed and erected for prospecting operations on the South Eureka property. With these works the ground can be explored to a depth of between 1200 and 1500 feet. The boiler and steam-power will be kept as a reserve in case of a break or failure in the water-power. Water power will be put in at once. To gain the necessary pressure of 180 feet the wheel will probably be located at the bottom of a gulch, and from thence the power will be transmitted by wire cable 500 feet to the hill on which the shaft will be located.

HARDENBURG.—A mishap occurred at this mine the latter part of last week. The mill was fixed in running order, and water was turned into the pipe, but before the full pressure was on the pipe burst in a number of places, showing that it was useless for the work demanded of it. It was old pipe, used on the Mello claim. It has all been taken up, and new pipe is being made by C. O. Mitchell in Sutter Creek. The disaster will delay the starting of the mill from 10 to 12 days.

CARRARA MARBLE CO.—The work of making the road from the quarry to the main county road was commenced last Monday. A Chichizola, the contractor, has a large force at work and intends pushing it to completion as soon as possible. An important item of news was received by parties interested in this quarry this week, to the effect that the managers of the company below had negotiated for the delivery by September next of \$20,000 worth of the marble, to be used at the Stanford University. The arrangements to this effect are reported to be as good as completed. A better advertisement for Amador marble could not be had than its use in a great public institution like the Stanford University.

BELMONT.—The Superintendent says: At this mine the surface tunnel is now in 280 feet, the last 100 feet all in ore. The 10-stamp mill is doing good work, being supplied with ore from tunnel level. The company are now figuring on a larger milling plant, as they have developed a large body of ore.

Butte.

BIG BEND.—*Nevada Transcript*, May 1: Work has been resumed on the Big Bend River mine, above Oroville, this summer. Dr. Pierce of Buffalo, New York, the president of the company having sent word to the foreman to prepare to commence again.

WILL RESUME.—It is said that the quartz mine near Forbestown, owned by W. W. Stow of San Francisco, and which was worked last summer, will resume operations again soon, and will work the ore by Huntington crushers, which are now on the way to the mine.

Calaveras.

SINKING.—*Calaveras Chronicle*, May 2: The work of sinking at the Smith mine near West Point is progressing steadily under the superintendency of Wm. Sales, Esq. The mine is supplied with steam hoisting works and all the necessary appliances for the development of the mine. The ore is said to be good and all indications point to a permanent piece of mining property.

MILL RUNNING.—The mill at the Sandy Bar mine has been running steadily since Tuesday of last week crushing rock from the Mammoth mine. Mr. E. H. Davison, who has the management of operations, informs us that the rock is looking well.

HALLOCK.—*Mt. Echo*, May 1: The work of erecting a 20-stamp mill on the Hallock mine, near this town, goes bravely on. Mr. Hallock evidently means business and doubtless will succeed. It is said that the sulphurets in this mine are of a higher grade than any in the county.

Nevada.

PEABODY.—*Grass Valley Union*, May 1: The new incline shaft on the Peabody mine, which was commenced a few weeks ago, has been sunk and timbered to a depth of 160 feet. The shaft is in three compartments, 14x5½ feet in the clear and has been timbered throughout, which shows that the work has been done with remarkable speed. The ground has been very favorable for sinking. Much credit is due to Supt. Tilley in having the work pushed with so much energy. The shaft has to be sunk to the depth of 240 altogether to connect with the lowest level of the mine.

WYOMING.—*Grass Valley Union*, April 29: The Wyoming M. Co. expects to commence putting up machinery for hoisting and pumping during next month.

NORTH BANNER.—A gold brick weighing 263 ounces was brought in from the North Banner mine yesterday, being a partial cleanup for the present month.

THE CROWN POINT mill is running steadily, night and day, on quartz from the New Eureka mine.

BRUNSWICK.—*Grass Valley Union*, May 2: Supt. Fitzgerald of the Brunswick mine, in his last letter to the home office, New York, says: Ledge in drifts is about the same, except in quality of quartz in the east, which has improved. Ledge not so wide but is liable to change for the better any time. I am nearing the chute above; expect to strike it in the next 50 feet; see no reason why I should not. I am following the ledge between two well-defined walls and am in good quartz all the way.

DOINGS OF PROSPECTORS.—*Nevada Transcript*, May 2: A test crushing of some ore from Red Hill is being made at Socklin's mill. Clemo & Co. are prospecting for quartz on the Half Mile House property. At the Centennial drift claim on the Washington ridge an upraise will be made next week in the hope of finding gravel. Bert Guild is taking some ore from the old Nicholson ledge near Chinatown. Ex-City Marshal Baldrige and a partner are working over some bedrock in the Manzanita claim, and they are just about making wages. The Mountain Chief is the name of a very promising quartz claim in Willow Valley, not far from the Deadwood mill, and which is worked by Joseph Dean

and Oliver Ragon with good results. Ore taken from it has milled as high as \$82 a ton. Recently J. C. Locklin has made arrangements to assist Messrs Dean and Ragon in going down on the ledge below water level, and Mr. Locklin's hoisting and pumping machinery is being put up on the claim. Steep Hollow is a lively section this spring. The Steep Hollow Co. is completing a road so as to get in supplies and tools. John Hussey has an encouraging quartz prospect. Beightol & Co. have gravel in their Bald Eagle claim, but are pushing their tunnel ahead with the hope of finding some good quartz.

Shasta.

COAL.—*Adin Argus*, April 30: About 20 miles this side of Anderson, Shasta county, has been discovered a coal mine which is attracting no little attention. While coming by the new discovery recently, H. S. Brown obtained a sample of the coal, which Mr. Leventon, the Lookout blacksmith, pronounces better than he has received from Sacramento.

Sierra.

A GOOD GRAVEL STRIKE.—*Nevada Transcript*, April 28: At the Occidental drift claim between the old Bald Mountain and the Bald Mountain Extension near Forest City, Sierra Co., Captain Bradbury ran a tunnel in a distance of 125 feet and then made an upraise, and recently struck gravel that prospects well. A company formerly spent many thousands dollars in the same ground without getting a prospect, the long tunnel they ran being to one side of the channel.

LONE STAR.—*Mt. Messenger*, May 2: The Lone Star Quartz M. Co., whose office is at Grass Valley, has had a survey made for a patent for its property situated in Gold Valley, twelve miles from Downieville. Al. Smith, Arthur Lamay and Charley Fricke, sinking a shaft at the lower end of Fournier's ranch, have gone through a pipeclay deposit and are probably, not far from bedrock. The Cleveland quartz mine, at the head of Nigger Canyon, is doing very well.

GOLD.—For a 24-days' run, the Mercer & Salinas quartz mine produced nearly three thousand dollars in gold. This is doing remarkably well, the working expenses being very light.

Trinity.

MINE BONDED.—*Trinity Journal*, May 2: Robert Woodburn of Lake Valley, El Dorado Co., was here this week taking a look at some mines. He was sufficiently impressed with the Fisher Gulch property to take a six months bond on it and will begin development work at once, erecting a mill on the mine during the summer if the prospects warrant such a move. Wm. Berry who came up with Mr. Woodburn will have charge of the work and will probably have everything ready for operation by next Monday.

Tulolumne.

HYDE.—*Union-Democrat*, May 2: The news from the Hyde mine, now called the Belle View, is favorable. The 10-stamp mill is yielding a good profit and 10 stamps more are to be at once added to the mill. The Mary Ellen, situated on the main Tulolumne river near Groveland, has been incorporated in San Francisco and work energetically started on it. The mine is looking well. The ground belonging to the company is very extensive, comprising some 12 claims of 1500 feet each, with a good millsite. Mill work on this mine, as well as assays of the ore, have given such good results that no doubt exists that the mine will prove a profitable property. Mr. Geo. Stayton returned from Gilroy last Wednesday, where he has been to confer with his associates in the Badger mine, situated near Jamestown in this county. The work of development on the mine will now proceed vigorously. Alexander McDonald, a mining capitalist of San Francisco, arrived in Sonora Wednesday. He has now in view the purchase of the rich river claim owned by Chas. Fitch and which is situated on the Stanislaus river at Byrne's Ferry. In the Little Bonanza mine, better known as the Colby, situated at the upper end of town, a rich strike was made this week. The Kanaka mine has now developed into a good paying property. The mill has been steadily at work for five months, and the value of the ore has been now determined by practical mill work and found to give a fine profit over all expenses of mining and milling. When five more stamps are added to the mill—and this will soon be done—the profits will be larger in proportion.

NEVADA.

Washoe District.

CON. CAL. & VA. MINE.—*Virginia Chronicle*, May 2: 1100 level: The blower station started in the south drift from the shaft station on this level has been completed and the blower and driving engine are now in place. We are still easing timbers and replacing broken caps in this drift. This work will be completed in four or five days, and then we will resume work in the face of the drift. 1500 level: The width and quality of the ore which is shown in the opening 43 feet above the sill floor of this level continues to hold good, and we continue to find this ore body extending to the northeast, and the ore there continues to be of fair quality. We are continuing to stoop out ore of good quality at the end of the crosscut run west from the north drift on the sill floor of this level. 1650 level: The usual quantity of ore has been extracted from the openings of this level, and we are continuing to extract ore of good quality in working out from the winze No. 2, at a point 35 feet above the sill floor of the 1750 level. Winze No. 3 has been sunk 23½ feet; total depth, 103½ feet, and connected with the crosscut run west from the southwest drift on the sill floor of the 1750 level. The end of the southwest drift on this level has been carried up 14 feet; total height, 55 feet, and some milling ore has been extracted therefrom, 1750 level: An upraise started near the face of the drift run southwest from the northwest drift from the main west drift from the C. & C. shaft has been carried up 16 feet on an ore streak from which some milling ore has been extracted. There has been extracted from all parts of the mine during the week 1,485 1190-2000 tons of ore, which was shipped to the Eureka mill. The average assay value of all of the ore worked at that mill during the week (1545 tons) was \$33 10 per ton. In addition to the Eureka mill, the Morgan mill commence working ore from this mine about May 10. Bullion now on hand in our assay office,

assay value, about \$30,000. Bullion shipped to Carson Mint, assay value, \$51,747.18.

OPHIR.—Have continued to extract ore from the upraise which was carried up from the drift run south from the drift run west from the winze 122 feet below the sill floor of the 1300 level. The ore which was stored in the mine is being hoisted to the surface, and there has been shipped to the Morgan mill during the week 157 tons of ore, on which the mill has commenced running.

OVERMAN.—Extracted from 1000 and 1100 levels 570 tons of ore. Car samples average \$15.48 per ton. Shipped to the Brunswick mill 598 tons of ore.

HALE & NORCROSS.—On the 1400 level of Hale & Norcross No. 5 east crosscut near the south boundary was advanced 15 feet; total length, 95 feet; face is in porphyry. The winze started at the end of No. 3 east crosscut is down 30 feet; the bottom continues in ore. The main incline is repaired and retimbered to the 1500 level, and will soon be able to reopen the 1500 level station.

KENTUCK CON.—Have started a west drift in the west ledge, 1000 level, from the top of the raise where it connected with the 950 winze; the face is in quartz assaying from \$5 to \$7 a ton.

UTAH.—South drift at the point where the raise was carried an incline has been sunk 22 feet, passing through vein porphyry and seams of quartz of low assay value.

OCCIDENTAL.—Extracting pay ore from the stopes on 350, 400 and 450 levels. The south drift from No. 1 upraise, 500 level, is in 77 feet in low-grade ore.

ALPHA AND EXCHEQUER.—But little work has been done in the above mines the past week, owing to repairs to the shaft.

SILVER HILL.—Northwest drift, 50-foot level, is out from the shaft 145 feet; face in porphyry. North crosscut, 160 level, is out from the winze 7½ feet; face in hard porphyry.

CHOLLAR.—The south lateral drift from the north line, 1400 level, is out 93 feet; face in porphyry. Extracted and sent to the mill during the past week 542 tons of ore, worth as per battery samples \$19.22 per ton.

POTOSI.—The south lateral drift from the winze station, 1300 level is out 120 feet; face in porphyry. The winze is down 41 feet below the 1400 level; the bottom is in clay and porphyry.

ANDES.—The east crosscut from north drift on the 420 level was extended 76 feet; formation somewhat softer than last report.

SIERRA NEVADA.—630 level: West crosscut No. 1 from the northwest drift 571 feet from the shaft, has been advanced 44 feet; total distance 315 feet. Formation somewhat softer than last report.

BEST & BELCHER.—1000 level: North drift has been cleaned and repaired 80 feet; total length, 600 feet. 1100 level: Northeast drift has been advanced 25 feet, through a soft porphyry; total length, 125 feet. West crosscut has been repaired 160 feet.

GOULD & CURRY.—200 level: Have extracted from the old stopes during the week 126 cars of ore. Sent to the Nevada mill 250 tons of ore; average battery assay for the month, \$22.

UNION CON.—East crosscut No. 2 on the 1465 level, started from the north lateral drift at a point 200 feet north from the south boundary line of the mine, has been extended 28 feet; total length, 87½ feet; passing through soft vein porphyry with some clay and fine lines of quartz.

ALTA.—Steam is up and the resumption of work in the mine has begun, and a prosperous run is looked to.

YELLOW JACKET.—The usual prospecting work is being done throughout the mine, and extracting some pay ore.

BELCHER.—Have stopped No. 3 west crosscut on the 300 level in the west ledge to permit the water to drain off, and have started a north drift from the main west crosscut from the shaft opposite the south lateral drift, same level; the face is in low grade.

CROWN POINT.—The 1000 level east crosscut is out 41 feet, having been extended 20 feet during the week; the face is in a mixture of porphyry and low-grade quartz.

CHALLENGE AND CONFIDENCE.—The joint Confidence and Challenge east crosscut on the 600 level is out 23 feet, having been commenced during the week; the face shows quartz having no value. The joint Challenge and Confidence north drift on the 1100 level is in 189 feet, 25 feet having been made during the week; the face shows quartz having no value.

SEG. BELCHER.—On the 600 level the east crosscut from the south lateral drift is out a distance of 290 feet, having been advanced 20 feet during the week. Have stopped it, and will start a west crosscut from the lateral drift at a point about midway in the ground.

JUSTICE.—The south winze on the 490 level is down 6½ feet. The bottom is in a mixture of quartz and porphyry, with streaks of ore running through it. The north drift on the 822 level is out 632 feet. The face is in quartz giving assays of from \$15 to \$25 per ton.

SAVAGE.—We have hoisted 653 cars of ore from the 500, 750, 800, 900 and 950 levels and from the intermediate drifts north and south from the winze below the 1300 level. Shipped to the Mexican mill 566 tons and milled 490 tons; average battery assay, \$17.30. We have haulion on hand amounting to \$23,100. On the 1100 level they are prospecting and drifting on the ore recently found, preparatory to more extensive explorations.

Cherry Creek District.

STAR.—White Pine News, May 2: At Cherry Creek, to the north of us, A. M. Ellsworth has the mill near the tunnel at the old Star mine completed and will soon commence working the dump. This may be the prelude to more extensive operations and better times for our neighbors down the valley.

Cottonwood District.

THE INGERSOLL MINE.—Mr. James Harvey of the Ingersoll mine in Cottonwood canyon, four miles south of Unionville, informs us that they have traced the ore on the surface for some 760 feet. They have run several drifts on the lode, being in ore most of the time. The lower tunnel is in 60 feet and about 280 feet below the upper works. They have sunk a winze 60 feet below water level, it being in good ore the entire depth. The ledge at that depth is 18 inches in width; the ore is a bright carbonate as they gain depth. This location is on the same belt with the once famous Moonlight lode, the ore of which

worked as high as \$2000 to the ton. It is supposed to be an extension of that vein.

Eagle District.

PART OF DEEP CREEK COUNTRY.—Salt Lake Tribune, May 2: John Tippet, recorder of Eagle mining district, in the Deep Creek country, arrived in the city yesterday. The district is some 25 or 30 miles southwest of the Deep Creek station, hence it is in White Pine county, Nevada, and embraces part of Eagle range, or Kern mountains. Mr. Tippet has lived there for the past seven years, all of which time he has been prospecting, working on his numerous claims and taking out enough ore to keep him and what help he hired. He has shipped mostly from his Harrison mine, located in granite, having a vein three to six feet wide and producing ore that went 300 to 500 ounces silver, with very little lead or copper. He ran a tunnel on this vein 100 feet, in ore all the way except some 10 or 15 feet. On his Anna he has a shaft down 60 feet and has taken 100 tons of ore out of the mine, which went 500 to 600 ounces in silver. The vein is 5½ to 6 feet wide, one-half being rich, while the other is second class, but with a mill would pay well to work. It is chloride ore, and hence cannot be concentrated without great loss. The Paymaster produces ore up to 150 ounces silver, 25 per cent lead and carries some iron. This vein is 10 or 12 feet wide and has been opened but little. But few persons are in Eagle as yet, probably 20 in all, who are prospecting and working on their claims.

Osceola District.

PLENTY OF WATER.—White Pine News, May 2: Osceola, on the south, is also receiving attention from Eastern capitalists. The Gravel Mining Co., with plenty of water this season, will turn out many shining bars of gold, and the dry-washers will add to the general output and prosperity of that district.

White Pine District.

AT HAMILTON.—White Pine News, May 2: Over at Hamilton, the old district is also claiming the attention of mining men of experience and capital, and it is not improbable that by the 1st of June some of the rich silver lead mines around White Pine mountain will have passed into the hands of San Francisco capitalists. Supt. William Read will also resume operations on the old Eberhardt tunnel. All this means a great revival of business for White Pine's first capital.

ARIZONA.

A GOOD PROSPECT.—*Tombstone Prospector*, May 1: Mulzar Osborn came in to-day from Dos Cabezas and reports some activity in that neighborhood. An eastern company has taken hold of the old Rouse claim on the road near Apache pass and have placed a whim on it. They will sink 100 feet and drift 50 feet each way for an interest. The shaft, when they took hold of the mine, was 50 feet deep and water hoisted there. The ledge there was three feet wide. At 60 feet, where they are at present, the ledge is five feet and widens as work progresses. If the mine looks well at 100 feet they propose to put up five or ten stamps on the mine. There is water in abundance at 10 feet right at the mine and plenty of wood. The ore milled \$8 without sorting at 50 feet, and also carries about nine ounces of silver.

A HUACHUCA PROSPECT.—*Tombstone Prospector*, May 2: A. Frowde who has a ranch in Miller canyon Huachuca mountains, brought in a sample from a ledge on the summit of the range for assay and is much pleased over the result. He has a shaft down 50 feet on the ledge and crosscuts showing 12 feet of ore. The samples were taken from the bottom of the shaft. One sample shows 22 per cent lead and 13 oz silver. The other gave 25 oz silver and 13 per cent lead and \$4 in gold. Mr. Frowde will endeavor to get some one to run a tunnel from the bottom of the mountain to tap the ledge. He estimates that such a tunnel driven 700 feet would strike the ledge at 1500 feet down and at the same time bring the ore out to a comparatively level country. There is water in abundance and some of the finest timber in Arizona at the mines. The ledge runs along the top of the mountain almost on the backbone and is a contact between lime and porphyry. Mr. Frowde also states that there are immense bodies of manganese ore close to these mines.

BRITISH COLUMBIA.

A GOLD INTEREST SOLD.—*Donald Truth*, May 2: An impression prevails on the outside that the mineral of the Kootenay Lake country is either silver-lead or silver-copper, and that gold is only found in combination with these minerals. This is a wrong impression. Lying between Eagle and Rover creeks and extending southward from Kootenay river is a belt in which over 100 hundred locations have been made. The ledges are well defined, as far as depth has been attained, and vary in width from 18 inches to 6 feet, and even wider. The ore is free milling on the surface, and carries from \$20 to \$750 to the ton in gold. The Poorman, on Eagle creek, the Whitewater, on Rover creek, the Royal Canadian, between Eagle and Forty-nine creeks, and the Wild Cat, near Eagle creek, are the best known of these gold properties. The Poorman's output last year yielded 330 to the ton, and a mill test of ore from the Whitewater gave a return of over \$100 in gold. Work is now being done on several of these claims, and the Poorman 10-stamp mill will be started up the first week in May. That they are attracting the attention of capitalists is evidenced by the fact that this week a quarter interest in the Wild Cat was sold for \$12,500 by Hugh McRae to R. C. Ferguson and R. G. Tatlow of Vancouver. H. H. Keefe still retains his half interest, and Mr. McRae a quarter. If arrangements can be made, 30 tons of ore now on the dump will be run through the Poorman mill to test its value and if a satisfactory return is had machinery will be placed on the property at once. The claim is opened up by over 200 feet of tunnels and crosscuts, and several thousand tons of ore are exposed. The width of the ledge is not known, only one wall being exposed by the work done. The vein matter is similar to that in the Poorman, that is, quartz carrying free gold and sulphurets.

NEW FINDS IN GOAT RIVER DISTRICT.—Reports from Goat River district are very encouraging. Several new discoveries have been made lately, chief among which, is one by C. C. Sproule and

George Long, at a point about half a mile above "Jap" King's Alice. The owners of the Alice have done considerable work this spring in making trails and roads.

DUST ARRIVING FROM HALL CREEK.—The first dust from Hall Creek placers came to Nelson this week, and is good-looking coarse gold. While no sluicing has been done on any of the claims, owing to the depth of snow, good headway is being made on drain ditches and other preparatory work. The boys on the ground are all jubilant, several of them claiming that the diggings are good for an ounce a day to the man.

WORK TO BE COMMENCED.—The provincial government has taken prompt action on a matter that concerns the mine owners of Toad Mountain district. Work is to be commenced at once on the wagon road from Nelson to the mines on Toad mountain.

COLORADO.

THE CRYSTAL PROPERTIES.—Aspen Times, May 1: T. O. Bryan came in from Crystal yesterday and gives the following information concerning the properties of that locality: The famous Black Queen mine is closed down owing to litigation, and the time of its resuming operations is a matter of conjecture. Cass and Ferris, of Aspen, are working a small force of men on the J. B. Wheeler claims, on Sheep mountain. Joe Paxton has at last struck it rich in the Illinois, and his friends congratulate him on his well deserved success. The Paymaster is now turning out some very rich ore, and bids fair to be a fine producer. The trail from Carbondale is again passable, and Crystal will now enjoy easy communication with the outside world.

DAKOTA.

BULLION.—Deadwood Pioneer, May 1: Two magnificent specimens of the recent strike in the Bullion mine at Galena were sent over yesterday by Superintendent Sprando, and placed on exhibition. One piece weighed about 200 pounds, and fairly glistened with galena and lead carbonates. It is stated that the ore will go 400 ounces of silver per ton, and from 50 to 60 per cent lead.

GARDEN CITY.—The erection of the Keystone chlorination works has set in activity the location and representation of claims in the Garden City district, and every day a number of location certificates are filed in the register's office from this district.

TIN.—Capt. Taylor is making satisfactory progress with his Nigger Hill tin mines. Ore of good quality is being piled up on the dump, charcoal is being burned, and the erection of the mill progressing as rapidly as possible.

IDAHO.

THE TRUMP.—Wood River Times, May 1: Work has been quietly prosecuted on the Trump mine, at the head of Rock creek, since last November. Capt. Black and his associates are now rewarded by the opening up of a large and rich body of heavy galena ore. The ore is a heavy galena carrying from 60 to 65 per cent lead and 100 ounces silver to the ton.

RED CLOUD ORE.—Mr. Brasse, the contractor, has resumed the hauling of Red Cloud ore to Hailley. He brought down 300 sacks last week and will continue to haul right along. He says that, as near as he can guess, there are between 300 and 500 tons on the dump, and an average of 10 tons is extracted daily.

BOISE BASIN.—Cor. Idaho Statesman, April 31: The placer mining season is opening up throughout the Basin with very good prospects. The water supply is very good but not as abundant as last year. Considerable snow remains in the mountains, which will prolong the water season and continue the supply for two or three months. Among the hydraulic claims in operation on this side of the Basin may be mentioned those of John Peeke and Ed Maloy & Co., at Cold Spring, Cramer & Trader and Van Tim & Lass, on Last Chance bar, John Riordan, in California gulch, Wm. Barker on Steamboat, White, Reel & Kearney, between Pine and Bannock creeks, Brockmiller & Spiero at Walla Walla flat, and Asbury Turner on Buena Vista bar. At Centerville Hon. Stephen Dempsey is tearing away the bank in his claim and several others on Grimes and Granite creeks have started up. At Idaho City, K. P. Plowman has water through his ditches and the two large chiefs will be in operation in the course of a few days. Hon. Ben Williams has a crew of men at work cleaning out his ditches at Pioneerville, but piling will not commence until about May 10th. Besides the claims mentioned there are many others of minor importance that will add largely to the gold product of the Basin this year. While the placer mining industry is waning it is still of considerable importance, and enables many owners of quartz prospects to keep up the assessment work and develop their veins. Our quartz interests for the present, while capital is slow about coming in, are dependent to no little extent upon the placer mines. Boise county can show a less number of failures for the number of mines worked than any other county in the State. The Gold Hill mill at Quartzburg, has run constantly for over 20 years, and there has hardly been a month that it has not paid more than expenses. The shaft of the Washington mine, in Gambrian district, has reached the 300-foot level below the bed of the creek. On the 200-foot level a vein of argentiferous ore from one foot to 18 inches in width has been developed a length of over 100 feet and the end is not yet. It is understood that the roasters will be erected this year, so that the silver can be treated. The Elmina mill at Banner, having run short of wood and salt, has closed down until the roads are passable, which will be about the 1st of June. The yield during the past year has been large, and since the closing up of the road in February, 80,000 ounces of silver has accumulated. Henry Whitney, Superintendent of a Boston company's mines between Grimes and Muddy creek above Pioneerville, will start up the new 20-stamp mill in two or three weeks. Wm. Sweet has started a new two-compartment shaft on a mine at the head of Big Muddy. He will sink it to a depth of 400 feet, and if the mine continues good at that depth, will develop it to the depth of 1000 feet by a tunnel from the Payette side of the mountain. The Gold Hill 25-stamp mill at Quartzburg, continues pounding away day and night on ore from the Pioneer mine. This is the largest vein now working in Boise county, being 60 feet between walls, which is milled

without assorting. Were this property in Colorado or Montana it would have a world-wide reputation.

LOWER CALIFORNIA.

MILL BURNED.—Lower Californian, May 30: Lane's mill burned down last evening at 5:15. The flames started from a fire in the forge and in ten minutes the building disappeared from the face of the earth. The mill had not been running yesterday. A large house near by was barely saved. The mill machinery, engine and boiler can be saved, making the net loss about \$2000. There was no insurance. Col. Lane will not rebuild. The Indian mine closed down permanently yesterday, and the pumps and machinery will be moved to the San David. The ledge pinched out. The Princess mine starts up soon. The ore in the Aurora has run out and sinking has commenced on the mine. Some fine-looking rock is being taken from the deepest shaft of the Aurora, and it not only pays well but has strong indications of silver. All the working mines of the Princess Co. are looking well and Captain Rodda keeps them going in full blast. The Princess mill works night and day on rock mainly from the Gold Tree. The other mines are being worked at present more for development and depth than for ore extraction. The El Paso mine and mill continue busy under Supt. McLaran. The vein develops well in size and richness. The Montezuma Co. is said to be preparing to resume work. The mine adjoins the San David on the flat between the Aurora and El Paso, and is very rich so far as prospect. Its location makes the water question of great importance, and large pumps are necessary on both it and the San David.

MONTANA.
